Subdural empyema	Usually elevated (100-300)	100-5000; PMNs predominate	100-500	Normal	No organisms on smear or culture of CSF unless meningitis also present; organisms found on tap of subdural fluid
Cerebral epidural abscess	Normal to slightly elevated	10-500; lymphocytes predominate	50-200	Normal	No organisms on smear or culture of CSF
Spinal epidural abscess	Usually low, with spinal block	10-100; lymphocytes predominate	50-400	Normal	No organisms on smear or culture of CSF
Chemical (drugs, dermoid cysts, myelography dye)	Usually elevated	100-1000 or more; PMNs predominate	50-100	Normal or slightly decreased	Epithelial cells may be seen within CSF by use of polarized light in some children with dermoids
Noninfectious Causes					
Sarcoidosis	Normal or elevated slightly	0-100; mononuclear	40-100	Normal	No specific findings
Systemic lupus erythematosus with CNS involvement	Slightly elevated	0-500; PMNs usually predominate; lymphocytes may be present	100	Normal or slightly decreased	No organisms on smear or culture; LE preparation may be positive; positive neuronal and ribosomal P protein antibodies in CSF
Tumor, leukemia	Slightly elevated to very high	0-100 or more; mononuclear or blast cells	50-1000	Normal to decreased (20-40)	Cytology may be positive

CHLAMYDIA TRACHOMATIS PCR

Test description: Test is performed on endocervical swab, urine, and intraurethral swab
Normal: Negative

CHLORIDE (serum)

Normal range: 95-105 mEq/L (95-105 mmol/L [CF: 1; SMI: 1 mmol/L])
Elevated in: Dehydration, excessive infusion of normal saline solution, cystic fibrosis (sweat test), hyperparathyroidism, renal tubular disease, metabolic acidosis, prolonged diarrhea, drugs (ammonium chloride administration, acetazolamide, boric acid, triamterene)
Decreased in: Congestive heart failure, syndrome of inappropriate antidiuretic hormone secretion, Addison's disease, vomiting, gastric suction, salt-losing nephritis, continuous infusion of D_5W, thiazide diuretic administration, diaphoresis, diarrhea, burns, diabetic ketoacidosis

CHLORIDE (sweat)

Normal: 0-40 mmol/L
Borderline/indeterminate: 41-60 mmol/L
Consistent with cystic fibrosis: >60 mmol/L
False low results can occur with edema, excessive sweating, and hypoproteinemia.

CHLORIDE, URINE

See URINE CHLORIDE

CHOLECYSTOKININ-PANCREOZYMIN (CCK, CCK-PZ)

Normal: <80 pg/ml
Elevated in: Pancreatic disease, celiac disease, gastric ulcer, postgastrectomy, IBS, fatty food intolerance

CHOLESTEROL, HIGH-DENSITY LIPOPROTEIN

See HIGH-DENSITY LIPOPROTEIN CHOLESTEROL

CHOLESTEROL, LOW-DENSITY LIPOPROTEIN

See LOW-DENSITY LIPOPROTEIN CHOLESTEROL

CHOLESTEROL, TOTAL

Normal range: Varies with age
Generally <200 mg/dl (<5.20 mmol/L [CF: 0.02586; SMI: 0.05 mmol/L])
Elevated in: Primary hypercholesterolemia, biliary obstruction, diabetes mellitus, nephrotic syndrome, hypothyroidism, primary biliary cirrhosis, high-cholesterol diet, pregnancy third trimester, myocardial infarction, drugs (steroids, phenothiazines, oral contraceptives)
Decreased in: Medications (statins, niacin), starvation, malabsorption, sideroblastic anemia, thalassemia, abetalipoproteinemia, hyperthyroidism, Cushing's syndrome, hepatic failure, multiple myeloma, polycythemia vera, chronic myelocytic leukemia, myeloid metaplasia, Waldenström's macroglobulinemia, myelofibrosis

CHORIONIC GONADOTROPINS, HUMAN (serum)

Normal range, serum: Female, premenopausal: <0.8 IU/L; postmenopausal <3.3 IU/L
Male: <0.7 IU/L
Elevated in:
Pregnancy, choriocarcinoma, gestational trophoblastic neoplasia (including molar gestations), placental site trophoblastic tumors; human antimouse antibodies (HAMA) can produce false serum assay for hCG.
The principal use of this test is to diagnose pregnancy. The concentration of hCG increases significantly during the initial 6 weeks of pregnancy. Peak values approaching 100,000 IU/L occur 60-70 days following implantation.
hCG levels generally double every 1-3 days. In patients with concentration <2000 IU/L, an increase of serum hCG <66% after 2 days is suggestive of spontaneous abortion or ruptured ectopic gestation.

TABLE 4-8 Characteristics of Coagulation Factors

Factor	Descriptive Name	Source	Approximate Half-Life (hr)	Function
I	Fibrinogen	Liver	120	Substrate for fibrin clot (CP)
II	Prothrombin	Liver (VKD)	60	Serine protease (CP)
V	Proaccelerin, labile factor	Liver	12-36	Cofactor (CP)
VII	Serum prothrombin conversion accelerator, proconvertin	Liver (VKD)	6	(?) Serine protease (EP)
VIII	Antihemophilic factor or globulin	Endothelial cells and (?) elsewhere	12	Cofactor (IP)
IX	Plasma thromboplastin component, Christmas factor	Liver (VKD)	24	Serine protease (IP)
X	Stuart-Prower factor	Liver (VKD)	36	Serine protease (CP)
XI	Plasma thromboplastin antecedent	(?) Liver	40-84	Serine protease (IP)
XII	Hageman factor	(?) Liver	50	Serine protease contact activation (IP)
XIII	Fibrin-stabilizing factor	(?) Liver	96-180	Transglutaminase (CP)
Prekallikrein	Fletcher factor	(?) Liver	?	Serine protease contact activation (IP)
High-molecular-weight kininogen	Fitzgerald factor, Flaujeac or Williams factor	(?) Liver	?	Cofactor, contact activation (IP)

Reprinted from Noble J (ed): *Primary care medicine,* ed 3, St Louis, 2001, Mosby.
CP, Common pathway; *EP,* extrinsic pathway; *IP,* intrinsic pathway; *VKD,* vitamin K dependent.

CHYMOTRYPSIN

Normal: <10 mcg/L
Elevated in: Acute pancreatitis, chronic renal failure, oral enzyme preparations, gastric cancer, pancreatic cancer
Decreased in: Chronic pancreatitis, late cystic fibrosis

CIRCULATING ANTICOAGULANT (lupus anticoagulant)

Normal: Negative
Detected in: Systemic lupus erythematosus, drug-induced lupus, long-term phenothiazine therapy, multiple myeloma, ulcerative colitis, rheumatoid arthritis, postpartum, hemophilia, neoplasms, chronic inflammatory states, AIDS, nephrotic syndrome

NOTE: The name is a misnomer because these patients are prone to hypercoagulability and thrombosis.

CK

See CREATINE KINASE

CLONIDINE SUPPRESSION TEST

Interpretation: Clonidine inhibits neurogenic catecholamine release and will cause a decrease in plasma norepinephrine into the reference interval in hypertensive subjects without pheochromocytoma.Test is performed by giving 4.3 mcg clonidine/kg orally after overnight fast. Norepinephrine is measured at 3 hr. Result should be within established reference range and decrease to <50% of baseline concentration. Lack of decrease in norepinephrine is suggestive of pheochromocytoma.

CLOSTRIDIUM DIFFICILE TOXIN ASSAY (stool)

Normal: Negative
Detected in: Antibiotic-associated diarrhea and pseudomembranous colitis

CO

See CARBOXYHEMOGLOBIN

COAGULATION FACTORS

See Table 4-8 for characteristics of coagulation factors.
Factor reference ranges:
V: >10%
VII: >10%
VIII: 50%-170%
IX: 60%-136%
X: >10%
XI: 50%-150%
XII: >30%

Table 4-9 describes screening laboratory results in coagulation factor deficiencies.

COLD AGGLUTININS TITER

Normal range: <1:32
Elevated in:
Primary atypical pneumonia (mycoplasma pneumonia), infectious mononucleosis, CMV infection
Others: hepatic cirrhosis, acquired hemolytic anemia, frostbite, multiple myeloma, lymphoma, malaria

COMPLEMENT

Normal range:
C3: 70-160 mg/dl (0.7-1.6 g/L [CF: 0.01; SMI: 0.1 g/L])
C4: 20-40 mg/dl (0.2-0.4 g/L [CF: 0.01; SMI: 0.1 g/L])

TABLE 4-9 Screening Laboratory Results in Coagulation Factor Deficiencies

Deficient Factor	Frequency	PT	PTT	TT
I (fibrinogen)	Rare	↑	↑	↑
II (prothrombin)	Very rare	↑	↑	↑
V 1:1,000,000	↑	↑	NL	
VII	1:500,000	↑	NL	NL
VIII	1:5000 (male)	NL	↑	NL
IX	1:30,000 (male)	NL	↑	NL
X 1:500,000	↑	↑	NL	
XI	Rare*	NL	↑	NL
XII or HMWK or PK†	Rare	NL	↑	NL
XIII	Rare	NL	NL	NL

Reprinted from Andreoli TE (ed): *Cecil essentials of medicine,* ed 5, Philadelphia, 2001, WB Saunders.
↑ Increased over normal range; *HMWK,* high-molecular-weight kininogen; *NL,* normal; *PK,* prekallikrein; *PT,* prothrombin time; *PTT,* partial thromboplastin time; *TT,* thrombin time.
*Except in those of Ashkenazi Jewish descent (approximately 4% are heterozygous for factor XI deficiency).
†Not associated with clinical bleeding.

Abnormal values:

Decreased C3: Active SLE, immune complex disease, acute glomerulonephritis, inborn C3 deficiency, membranoproliferative glomerulonephritis, infective endocarditis, serum sickness, autoimmune/chronic active hepatitis

Decreased C4: Immune complex disease, active SLE, infective endocarditis, inborn C4 deficiency, hereditary angioedema, hypergammaglobulinemic states, cryobulinemic vasculitis

Table 4-10 describes complement deficiency states.

COMPLETE BLOOD COUNT (CBC)

White blood cells 3200-9800 mm^3 (3.2-9.8 $\times$ 10^9/L [CF: 0.001; SMI: 0.1 $\times$ 10^9/L])

Red blood cells
- Male: 4.3-5.9 $\times$ $10^6/mm^3$ (4.3-5.9 $\times$ 10^{12}/L [CF: 0.001; SMI: 0.1 $\times$ 10^{12}/L])
- Female: 3.5-5 $\times$ $10^6/mm^3$ (3.5-5 $\times$ 10^{12}/L [CF: 0.001; SMI: 0.1 $\times$ 10^{12}/L])

Hemoglobin
- Male: 13.6-17.7 g/dl (136-172 g/L [CF: 10; SMI: 1 g/L])
- Female: 12-15 g/dl (120-150 g/L [CF: 10; SMI: 1 g/L])

Hematocrit
- Male: 39%-49% (0.39-0.49 [CF: 0.01; SMI: 0.01])
- Female: 33%-43% (0.33-0.43 [CF: 0.01; SMI: 0.01])

Mean corpuscular volume (MCV): 76-100 μm^3 (76-100 fL [CF: 1; SMI: 1 fL])

TABLE 4-10 Complement Deficiency States

Component	No. of Reported Patients	Mode of Inheritance	Functional Defects	Disease Associations
Classic Pathway				
C1qrs	31	ACD	Impaired IC handling, delayed C′ activation, impaired immune response	CVD, 48%; infection (encapsulated bacteria), 22%; both, 18%; healthy, 12%
C4	21	ACD	Impaired C′ activation in absence of specific antibody	Infection (meningococcal), 74%; healthy, 26%
C2	109	ACD		
Alternative pathway				
D	3	ACD	Impaired IC handling, opson/phag; granulocytosis, CTX, immune response and absent SBA	CVD, 79%; recurrent infection (encapsulated bacteria), 71%
P	70	XL		
Junction of classic and alternative pathways				
C3	19	ACD	Impaired CTX; absent SBA	Infection (*Neisseria,* primarily meningococcal), 58%; CVD, 4%
Terminal components				
C5	27	ACD	Absent SBA	Both, 1%
C6	77	ACD		Healthy, 25%
C7	73	ACD		
C8	73	ACD		
C9	165	ACD	Impaired SBA	Healthy, 91%; infection, 9%
Plasma proteins regulating C′ activation				
C1-INH	Many	AD	Uncontrolled generation of an inflammatory mediator on C′ activation	Hereditary angioedema
H	13	Acq	Uncontrolled AP activation → low C3	CVD, 40%; CVD plus infection (encapsulated bacteria), 40%; healthy, 20%
I	14	ACD	Uncontrolled AP activation → low C3	Infection (encapsulated bacteria), 100%
Membrane proteins regulating C′ activation	Many	Acq	Impaired regulation of C3b and C8 deposited on host RBCs; PMN, platelets → cell lysis	Paroxysmal nocturnal hemoglobinuria
Decay-accelerating factor				
Homologous restriction factor				
CD59	>20	ACD	Impaired PMN adhesive functions (i.e., margination), CTX, C3bi-mediated opson/phag	Infection (*Staphylococcus aureus, Pseudomonas* spp.), 100%
CR3 autoantibodies				
C3 nephritic factors	>59	Acq	Stabilize AP, convertase → low C3	MPGN, 41%; PLD, 25%; infection (encapsulated bacteria), 16%; MPGN plus PLD, 10%; PLD plus infection, 5%; MPGN plus PLD plus infection, 3%; MPGN plus infection, 2%
C4 nephritic factor		Acq	Stabilize CP, C3 convertase → low C3	Glomerulonephritis, 50%; CVD, 50%

Reprinted from Mandell GL: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 6, New York, 2005, Churchill Livingstone.

ACD, Autosomal codominant; *Acq,* acquired; *AD,* autosomal dominant; *AP,* alternative pathway; *C′,* complement; *CP,* classic pathway; *CTX,* chemotaxis; *CVD,* collagen-vascular disease; *IC,* immune complex, *MPGN,* membranoproliferative glomerulonephritis; *PLD,* partial lipodystrophy; *PMN,* polymorphonuclear neutrophil; *RBCs,* red blood cells; *SBA,* serum bactericidal activity; *XL,* X-linked.

Mean corpuscular hemoglobin (MCH): 27-33 pg (27-33 pg [CF: 1; SMI: 1 pg])
Mean corpuscular hemoglobin concentration (MCHC): 33-37 g/dl (330-370 g/L [CF: 10; SMI: 10 g/L])
Red blood cell distribution width index (RDW): 11.5%-14.5%
Platelet count: 130-400 $\times$ $10^3/mm^3$ (130-400 $\times$ 10^9/L [CF: 1; SMI: 5 $\times$ 10^9/L])
Differential:
2-6 stabs (bands, early mature neutrophils)
60-70 segs (mature neutrophils)
1-4 eosinophils
0-1 basophils
2-8 monocytes
25-40 lymphocytes

CONJUGATED BILIRUBIN

See BILIRUBIN, DIRECT

COOMBS, DIRECT

Normal: Negative
Positive: Autoimmune hemolytic anemia, erythroblastosis fetalis, transfusion reactions, drugs (α-methyldopa, penicillins, tetracycline, sulfonamides, levodopa, cephalosporins, quinidine, insulin)
False-positive: May be seen with cold agglutinins

COOMBS, INDIRECT

Normal: Negative
Positive: Acquired hemolytic anemia, incompatible cross-matched blood, anti-Rh antibodies, drugs (methyldopa, mefenamic acid, levodopa)

COPPER (serum)

Normal range: 70-140 μg/dl (11-22 μmol/L [CF: 0.1574, SMI: 0.2 μmol/L])
Decreased in: Wilson's disease, Menkes' syndrome, malabsorption, malnutrition, nephrosis, total parenteral nutrition, acute leukemia in remission
Elevated in: Aplastic anemia, biliary cirrhosis, systemic lupus erythematosus, hemochromatosis, hyperthyroidism, hypothyroidism, infection, iron deficiency anemia, leukemia, lymphoma, oral contraceptives, pernicious anemia, rheumatoid arthritis

COPPER, URINE

See URINE COPPER

CORTICOTROPIN RELEASING HORMONE (CRH) STIMULATION TEST

Normal: A dose of 0.5 mg of dexamethasone is given every 6 hours for 2 days; 2 hours after last dose 1 mcg/kg CRH is given IV. Samples are drawn after 15 min. Normally there is a twofold to fourfold increase in mean baseline concentration of ACTH or cortisol. Cortisol >1.4 mcg/L is virtually 100% specific and 100% diagnostic.
Interpretation:
Normal or exaggerated response: Pituitary Cushing's disease
No response: Ectopic ACTH-secreting tumor
A positive response to CRH or a suppressed response to high-dose dexamethasone has a 97% positive predictive value for Cushing's disease. However, a lack of response to either test excludes Cushing's disease in only 64%-78% of patients. When the tests are considered together, negative responses from both have a 100% predictive value for ectopic ACTH secretion.

CORTISOL, PLASMA

Normal range: Varies with time of collection (circadian variation):
8 AM: 4-19 μg/dl (110-520 nmol/L [CF: 27.59; SMI: 10 nmol/L])
4 PM: 2-15 μg/dl (50-410 nmol/L [CF: 27.59; SMI: 10 nmol/L])
Elevated in: Ectopic adrenocorticotropic hormone production (i.e., oat cell carcinoma of lung), loss of normal diurnal variation, pregnancy, chronic renal failure, iatrogenic, stress, adrenal or pituitary hyperplasia, or adenomas
Decreased in: Primary adrenocortical insufficiency, anterior pituitary hypofunction, secondary adrenocortical insufficiency, adrenogenital syndromes

C-PEPTIDE

Elevated in: Insulinoma, sulfonylurea administration
Decreased in: Insulin-dependent diabetes mellitus, factitious insulin administration

CPK

See CREATINE KINASE

C-REACTIVE PROTEIN

Normal range: 6.8-820 μg/dl (68-8200 μg/L [CF: 10; SMI: 10 μg/L])
Elevated in: Rheumatoid arthritis, rheumatic fever, inflammatory bowel disease, bacterial infections, myocardial infarction, oral contraceptives, third trimester of pregnancy (acute phase reactant), inflammatory and neoplastic diseases

C-REACTIVE PROTEIN, HIGH SENSITIVITY (hs-CRP, cardio-CRP)

This is a cardiac risk marker. It is increased in patients with silent atherosclerosis years before a cardiovascular event and is independent of cholesterol level and other lipoproteins. It can be used to help stratify cardiac risk.
INTERPRETATION OF RESULTS:

Cardio-CRP result (mg/L)	*Risk*
0.6	Lowest risk
0.7-1.1	Low risk
1.2-1.9	Moderate risk
2.0-3.8	High risk
3.9-4.9	Highest risk
$\geq$5.0	Results may be confounded by acute inflammatory disease. If clinically indicated, a repeat test should be performed in 2 or more weeks.

CREATINE KINASE (CK, CPK)

Normal range: 0-130 U/L (0-2.16 μkat/L [CF: 0.01667; SMI: 0.01 μkat/L])
Elevated in: Myocardial infarction, myocarditis, rhabdomyolysis, myositis, crush injury/trauma, polymyositis, dermatomyositis, vigorous exercise, muscular dystrophy, myxedema, seizures, malignant hyperthermia syndrome, IM injections, cerebrovascular accident, pulmonary embolism and infarction, acute dissection of aorta
Decreased in: Steroids, decreased muscle mass, connective tissue disorders, alcoholic liver disease, metastatic neoplasms

CREATINE KINASE ISOENZYMES

CK-BB:
Elevated in: Cerebrovascular accident, subarachnoid hemorrhage, neoplasms (prostate, gastrointestinal tract, brain, ovary, breast, lung), severe shock, bowel infarction, hypothermia, meningitis
CK-MB:
Elevated in: Myocardial infarction (MI), myocarditis, pericarditis, muscular dystrophy, cardiac defibrillation, cardiac surgery, extensive rhabdomyolysis, strenuous exercise (marathon runners), mixed connective tissue disease, cardiomyopathy, hypothermia

NOTE: CK-MB exists in the blood in two subforms. MB_2 is released from cardiac cells and converted in the blood to MB_1. Rapid assay of CK-MB subforms can detect MI (CK-MB_2 $\geq$1.0 U/L, with a ratio of CK-MB_2/CK-MB_1 $\geq$1.5) within 6 hours of onset of symptoms.

Fig. 4-2 illustrates the time course of CK, AST, troponins, and LDH activity after acute MI.

CK-MM:
Elevated in: Crush injury, seizures, malignant hyperthermia syndrome, rhabdomyolysis, myositis, polymyositis, dermatomyositis, vigorous exercise, muscular dystrophy, IM injections, acute dissection of aorta

CREATININE (serum)

Normal range: 0.6-1.2 mg/dl (50-110 μmol/L [CF: 88.4; SMI: 10 μmol/L])
Elevated in: Renal insufficiency (acute and chronic), decreased renal perfusion (hypotension, dehydration, congestive heart failure), urinary tract infection, rhabdomyolysis, ketonemia

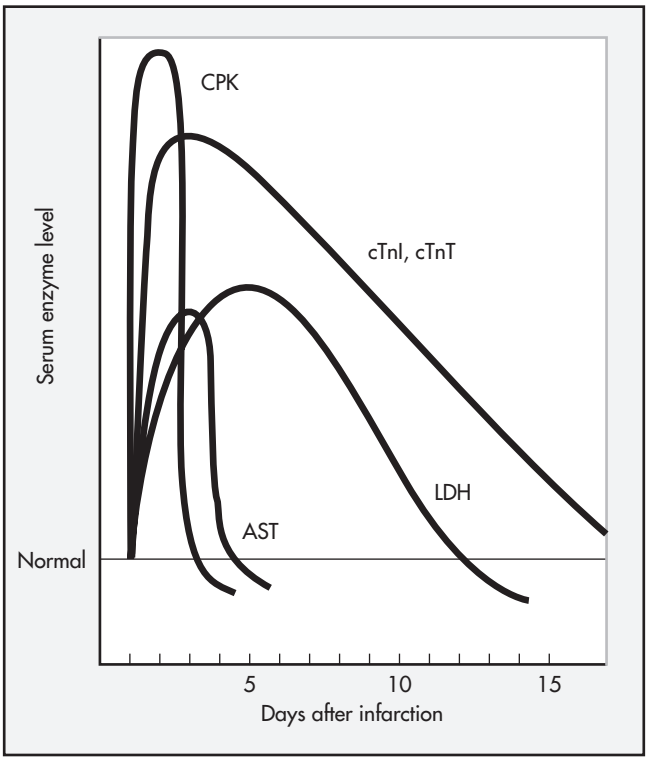

FIGURE 4-2 Evaluation of creatine kinase elevation. *CBC,* Complete blood count; *CK,* creatine kinase; *EMG,* electromyography. (Reprinted from Greene HL, Johnson WP, Lemcke D [eds]: *Decision making in medicine,* ed 2, St Louis, 1998, Mosby.)

Drugs (antibiotics [aminoglycosides, cephalosporins], hydantoin, diuretics, methyldopa)
Falsely elevated in: Diabetic ketoacidosis, administration of some cephalosporins (e.g., cefoxitin, cephalothin)
Decreased in: Decreased muscle mass (including amputees and older persons), pregnancy, prolonged debilitation

CREATININE CLEARANCE

Normal range: 75-124 ml/min (1.24-2.08 ml/sec [CF: 0.01667; SMI: 0.02 ml/sec])

Box 4-1 describes a formula for calculation of creatinine clearance.

The Cockcroft-Gault formula to calculate creatinine clearance is described in Box 4-2.

BOX 4-1 Calculation of the Creatinine Clearance

$C_{cr} = U_{cr} \times V/P_{cr}$
where C_{cr} = clearance of creatinine (ml/min)
U_{cr} = urine creatinine (mg/dl)
V = volume of urine (ml/min) (for 24-hr volume: divide by 1440)
P_{cr} = plasma creatinine (mg/dl)
Normal range: 95 to 105 ml/min/1.75m^2

BOX 4-2 Cockcroft-Gault Formula to Calculate Creatinine Clearance (C_{cr})

$$C_{cr} = \frac{(140 - \text{age in year}) \times (\text{lean body weight in kg})}{S_{cr} \text{ in mg/dl} - 72}$$

Elevated in: Pregnancy, exercise
Decreased in: Renal insufficiency, drugs (cimetidine, procainamide, antibiotics, quinidine)

CREATININE, URINE

See URINE CREATININE

CRYOGLOBULINS (serum)

Normal range: Not detectable
Present in: Collagen vascular diseases, chronic lymphocytic leukemia, hemolytic anemias, multiple myeloma, Waldenström's macroglobulinemia, chronic active hepatitis, Hodgkin's disease

CRYPTOSPORIDIUM ANTIGEN BY EIA (stool)

Normal range: Not detected
Present in: Cryptosporidiosis

CSF

See CEREBROSPINAL FLUID

CYSTATIN C

Normal: Cystatin C is a cysteine protease inhibitor that is produced at a constant rate by all nucleated cells. It is freely filtered by the glomerulus and reabsorbed (but not secreted) by the renal tubules with no extrarenal excretion. Its concentration is not affected by diet, muscle mass, or acute inflammation. Normal range when measured by particle-enhanced nephelometric immunoassay (PENIA) is <0.28 mg/L.
Elevated in: Renal disorders. Good predictor of the severity of acute tubular necrosis. Cystatin C increases more rapidly than creatinine in the early stages of GFR impairment. The cystatin C concentration is an independent risk factor for heart failure in older adults and appears to provide a better measure of risk assessment than the serum creatinine concentration.

CYSTIC FIBROSIS PCR

Test description: Test can be performed on whole blood or tissue. Common mutations in the cystic fibrosis transmembrane regulator (CFTR) gene can be used to detect 75%-80% of mutant alleles.

CYTOMEGALOVIRUS BY PCR

Test description: Test can be performed on whole blood, plasma, or tissue. Qualitative PCR is highly sensitive but may not be able to differentiate between latent and active infection.

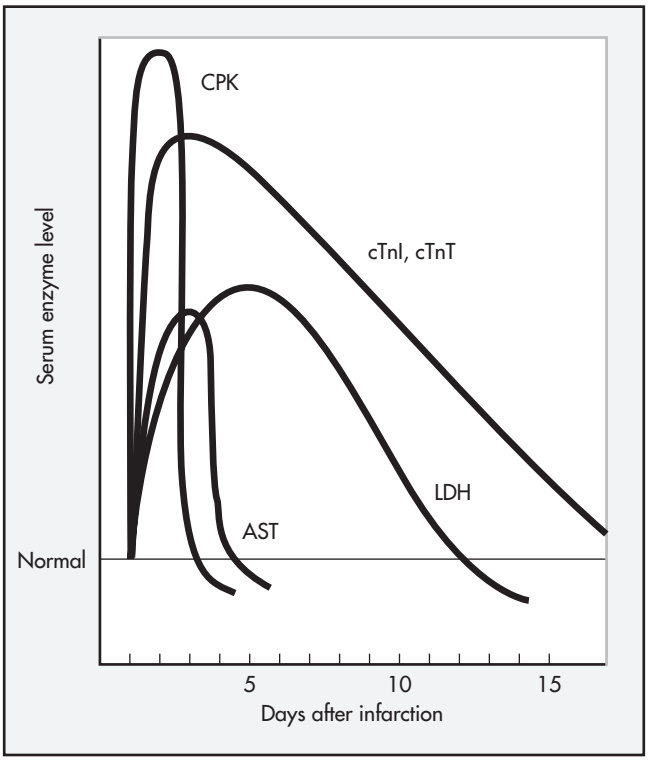

FIGURE 4-2 Evaluation of creatine kinase elevation. *CBC,* Complete blood count; *CK,* creatine kinase; *EMG,* electromyography. (Reprinted from Greene HL, Johnson WP, Lemcke D [eds]: *Decision making in medicine,* ed 2, St Louis, 1998, Mosby.)

Drugs (antibiotics [aminoglycosides, cephalosporins], hydantoin, diuretics, methyldopa)
Falsely elevated in: Diabetic ketoacidosis, administration of some cephalosporins (e.g., cefoxitin, cephalothin)
Decreased in: Decreased muscle mass (including amputees and older persons), pregnancy, prolonged debilitation

CREATININE CLEARANCE

Normal range: 75-124 ml/min (1.24-2.08 ml/sec [CF: 0.01667; SMI: 0.02 ml/sec])

Box 4-1 describes a formula for calculation of creatinine clearance.

The Cockcroft-Gault formula to calculate creatinine clearance is described in Box 4-2.

BOX 4-1 Calculation of the Creatinine Clearance

$C_{cr} = U_{cr} \times V/P_{cr}$
where C_{cr} = clearance of creatinine (ml/min)
U_{cr} = urine creatinine (mg/dl)
V = volume of urine (ml/min) (for 24-hr volume: divide by 1440)
P_{cr} = plasma creatinine (mg/dl)
Normal range: 95 to 105 ml/min/1.75m^2

BOX 4-2 Cockcroft-Gault Formula to Calculate Creatinine Clearance (C_{cr})

$$C_{cr} = \frac{(140 - \text{age in year}) \times (\text{lean body weight in kg})}{S_{cr} \text{ in mg/dl} - 72}$$

Elevated in: Pregnancy, exercise
Decreased in: Renal insufficiency, drugs (cimetidine, procainamide, antibiotics, quinidine)

CREATININE, URINE

See URINE CREATININE

CRYOGLOBULINS (serum)

Normal range: Not detectable
Present in: Collagen vascular diseases, chronic lymphocytic leukemia, hemolytic anemias, multiple myeloma, Waldenström's macroglobulinemia, chronic active hepatitis, Hodgkin's disease

CRYPTOSPORIDIUM ANTIGEN BY EIA (stool)

Normal range: Not detected
Present in: Cryptosporidiosis

CSF

CYSTATIN C

Normal: Cystatin C is a cysteine protease inhibitor that is produced at a constant rate by all nucleated cells. It is freely filtered by the glomerulus and reabsorbed (but not secreted) by the renal tubules with no extrarenal excretion. Its concentration is not affected by diet, muscle mass, or acute inflammation. Normal range when measured by particle-enhanced nephelometric immunoassay (PENIA) is <0.28 mg/L.
Elevated in: Renal disorders. Good predictor of the severity of acute tubular necrosis. Cystatin C increases more rapidly than creatinine in the early stages of GFR impairment. The cystatin C concentration is an independent risk factor for heart failure in older adults and appears to provide a better measure of risk assessment than the serum creatinine concentration.

CYSTIC FIBROSIS PCR

Test description: Test can be performed on whole blood or tissue. Common mutations in the cystic fibrosis transmembrane regulator (CFTR) gene can be used to detect 75%-80% of mutant alleles.

CYTOMEGALOVIRUS BY PCR

Test description: Test can be performed on whole blood, plasma, or tissue. Qualitative PCR is highly sensitive but may not be able to differentiate between latent and active infection.

D-DIMER

Normal range: <0.5 mcg/ml
Elevated in:
DVT, pulmonary embolism, high levels of rheumatoid factor, activation of coagulation and fibrolytic system from any cause
D-dimer assay by ELISA assists in the diagnosis of DVT and pulmonary embolism. This test has significant limitations because it can be elevated whenever the coagulation and fibrinolytic systems are activated and can also be falsely elevated with high rheumatoid factor levels.

DEHYDROEPIANDROSTERONE SULFATE

Normal:

Males:	
Ages 19-30:	125-619 mcg/dl
31-50:	59-452 mcg/dl
51-60:	20-413 mcg/dl
61-83:	10-285 mcg/dl
Females:	
Ages 19-30:	29-781 mcg/dl
31-50:	12-379 mcg/dl
Postmenopausal:	30-260 mcg/dl

Elevated in: Hirsutism, congenital adrenal hyperplasia, adrenal carcinomas, adrenal adenomas, polycystic ovary syndrome, ectopic ACTH-producing tumors, Cushing's disease, spironolactone

DEHYDROTESTOSTERONE (serum, urine)

Normal:
Serum: Males: 30-85 ng/dl; females: 4-22 ng/dl
Urine, 24 h: Males: 20-50 mcg/day; females: <8 mcg/day
Elevated in: Hirsutism
Decreased in: 5-α-reductase deficiency, hypogonadism

DEOXYCORTICOSTERONE (11-deoxycorticosterone, DOC) (serum)

Normal: 2-19 ng/dl. Normal secretion depends on ACTH and is suppressible by dexamethasone.
Elevated in: Adrogenital syndromes due to 17- and 11-hydroxylase deficiencies, pregnancy
Decreased in: Preeclampsia

DEXAMETHASONE SUPPRESSION TEST, OVERNIGHT

Normal: Test is performed by giving 1 mg dexamethasone orally at 11 PM and measuring serum cortisol at 8 AM the following morning. Normal response is cortisol suppression to <3 mcg/dl; If dose of 4 mg dexamethasone is given, cortisol suppression will be to <50% of baseline.
Interpretation: Cushing's syndrome (>10 mcg/dl), endogenous depression (half of patients suppress test values >5 mcg/dl). Most patients with pituitary Cushing's disease demonstrate suppression, whereas patients with adrenal adenoma, carcinoma, and ectopic ACTH-producing tumors do not.

DIGOXIN

Normal therapeutic range: 0.5-2 ng/ml
Elevated in: Impaired renal function, excessive dosing, concomitant use of quinidine, amiodarone, verapamil, fluoxetine, nifedipine. Toxicity may occur at a lower blood concentration in the presence of hypokalemia, hypomagnesemia, and hypercalcemia.

DILANTIN

See PHENYTOIN

DISACCHARIDE ABSORPTION TESTS

Normal: Test is used to diagnose malabsorption due to disaccharide deficiency. It is performed by giving disaccharide orally 1 g/kg body weight to a total of 25 g. Blood is drawn at 0, 30, 60, 90, and 120 min. Normal response is a change in glucose from fasting value >30 mg/dl, inconclusive when increase is 20-30 mg/dl, abnormal when increase is <20 mg/dl. Test can also be performed by measuring air at 0, 30, 60, 90, and 120 min. Normal is H_2 >20 ppm above baseline level before a colonic response.
Decreased in: Disaccharide deficiency (lactose, fructose, sorbitol), celiac disease, sprue, acute gastroenetetitis

DOC

See DEOXYCORTICOSTERONE

DONATH-LANDSTEINER (D-L) TEST FOR PAROXYSMAL COLD HEMOGLOBINURIA

Normal: No hemolysis
Interpretation: Hemolysis indicates presence of bithermic cold hemolysins or Donath-Landsteiner antibodies (D-L Ab)

DOPAMINE

Normal range: 175 pg/ml
Elevated in: Pheochromocytomas, neuroblastomas, stress, vigorous exercise, certain foods (bananas, chocolate, coffee, tea, vanilla)

d-XYLOSE ABSORPTION

Normal range: 21%-31% excreted in 5 hours
Decreased in: Malabsorption syndrome

d-XYLOSE ABSORPTION TEST

Normal range:
URINE: ≥4 g/5 hours (5-hour urine collection in adults >12 years [25-g dose])
SERUM: ≥25 mg/dl (adult, 1 h, 25-g dose, normal renal function)
Normal results: In patients with malabsorption, normal results suggest pancreatic disease as an etiology of the malabsorption.
Abnormal results: Celiac disease, Crohn's disease, tropical sprue, surgical bowel resection, AIDS. False-positives can occur with decreased renal function, dehydration/hypovolemia, surgical blind loops, decreased gastric emptying, vomiting.

DEHYDROTESTOSTERONE (serum, urine)

Normal:
Serum: Males: 30-85 ng/dl; females: 4-22 ng/dl
Urine, 24 h: Males: 20-50 mcg/day; females: <8 mcg/day
Elevated in: Hirsutism
Decreased in: 5-α-reductase deficiency, hypogonadism

DEOXYCORTICOSTERONE (11-deoxycorticosterone, DOC) (serum)

Normal: 2-19 ng/dl. Normal secretion depends on ACTH and is suppressible by dexamethasone.
Elevated in: Adrogenital syndromes due to 17- and 11-hydroxylase deficiencies, pregnancy
Decreased in: Preeclampsia

DEXAMETHASONE SUPPRESSION TEST, OVERNIGHT

Normal: Test is performed by giving 1 mg dexamethasone orally at 11 PM and measuring serum cortisol at 8 AM the following morning. Normal response is cortisol suppression to <3 mcg/dl; If dose of 4 mg dexamethasone is given, cortisol suppression will be to <50% of baseline.
Interpretation: Cushing's syndrome (>10 mcg/dl), endogenous depression (half of patients suppress test values >5 mcg/dl). Most patients with pituitary Cushing's disease demonstrate suppression, whereas patients with adrenal adenoma, carcinoma, and ectopic ACTH-producing tumors do not.

DIGOXIN

Normal therapeutic range: 0.5-2 ng/ml
Elevated in: Impaired renal function, excessive dosing, concomitant use of quinidine, amiodarone, verapamil, fluoxetine, nifedipine. Toxicity may occur at a lower blood concentration in the presence of hypokalemia, hypomagnesemia, and hypercalcemia.

DILANTIN

See PHENYTOIN

DISACCHARIDE ABSORPTION TESTS

Normal: Test is used to diagnose malabsorption due to disaccharide deficiency. It is performed by giving disaccharide orally 1 g/kg body weight to a total of 25 g. Blood is drawn at 0, 30, 60, 90, and 120 min. Normal response is a change in glucose from fasting value >30 mg/dl, inconclusive when increase is 20-30 mg/dl, abnormal when increase is <20 mg/dl. Test can also be performed by measuring air at 0, 30, 60, 90, and 120 min. Normal is H_2 >20 ppm above baseline level before a colonic response.
Decreased in: Disaccharide deficiency (lactose, fructose, sorbitol), celiac disease, sprue, acute gastroenetetitis

DOC

See DEOXYCORTICOSTERONE

DONATH-LANDSTEINER (D-L) TEST FOR PAROXYSMAL COLD HEMOGLOBINURIA

Normal: No hemolysis
Interpretation: Hemolysis indicates presence of bithermic cold hemolysins or Donath-Landsteiner antibodies (D-L Ab)

DOPAMINE

Normal range: 175 pg/ml
Elevated in: Pheochromocytomas, neuroblastomas, stress, vigorous exercise, certain foods (bananas, chocolate, coffee, tea, vanilla)

d-XYLOSE ABSORPTION

Normal range: 21%-31% excreted in 5 hours
Decreased in: Malabsorption syndrome

d-XYLOSE ABSORPTION TEST

Normal range:
URINE: ≥4 g/5 hours (5-hour urine collection in adults >12 years [25-g dose])
SERUM: ≥25 mg/dl (adult, 1 h, 25-g dose, normal renal function)
Normal results: In patients with malabsorption, normal results suggest pancreatic disease as an etiology of the malabsorption.
Abnormal results: Celiac disease, Crohn's disease, tropical sprue, surgical bowel resection, AIDS. False-positives can occur with decreased renal function, dehydration/hypovolemia, surgical blind loops, decreased gastric emptying, vomiting.

ELECTROPHORESIS, HEMOGLOBIN

See HEMOGLOBIN ELECTROPHORESIS

ELECTROPHORESIS, PROTEIN

See PROTEIN ELECTROPHORESIS

ENA COMPLEX

See EXTRACTABLE NUCLEAR ANTIGEN

ENDOMYSIAL ANTIBODIES

Normal: Not detected
Present in: Celiac disease, dermatitis herpetiformis

EOSINOPHIL COUNT

Normal range: 1%-4% eosinophils (0-440/mm^3)
Elevated in:
HELMINTHIC PARASITES
Ascaris lumbricoides (invasive larval stage)
Hookworms (invasive larval stage)
Strongyloides stercoralis (initial infection and autoinfection)
Trichinosis
Filariasis
Echinococcus granulosus and *E. multilocularis*
Toxocara species
Animal hookworms
Angiostrongylus cantonensis and *A. costaricensis*
Schistosomiasis
Liver flukes
Fasciolopsis buski
Anisakiasis
Capillaria philippinensis
Paragonimus westermani
"Tropical eosinophilia" (unidentified microfilariae)
OTHER INFECTIONS/INFESTATIONS
Pulmonary aspergillosis
Severe scabies
ALLERGIES
Asthma
Hay fever
Drug reactions
Atopic dermatitis
AUTOIMMUNE AND RELATED DISORDERS
Polyarteritis nodosa
Necrotizing vasculitis
Eosinophilic fasciitis
Pemphigus
NEOPLASTIC DISEASES
Hodgkin's disease
Mycosis fungoides
Chronic myelocytic leukemia
Eosinophilic leukemia
Polycythemia vera
Mucin-secreting adenocarcinomas
IMMUNODEFICIENCY STATES
Hyperimmunoglobulin E with recurrent infection
Wiskott-Aldrich syndrome
OTHER
Addison's disease
Inflammatory bowel disease
Dermatitis herpetiformis
Toxic/chemical syndrome

Eosinophilic myalgia syndrome, tryptophan, toxic oil syndrome
Hypereosinophilic syndrome (unknown etiology)

EPINEPHRINE, PLASMA

Normal range: 0-90 pg/ml
Elevated in: Pheochromocytomas, neuroblastomas, stress, vigorous exercise, certain foods (bananas, chocolate, coffee, tea, vanilla), hypoglycemia

EPSTEIN-BARR VIRUS SEROLOGY

Normal range: IgG anti-VCA <1:10 or negative
Abnormal:
IgG anti-VCA >1:10 or positive indicates either current or previous infection
IgM anti-VCA >1:10 or positive indicates current or recent infection
Anti-EBNA ≥1.5 or positive indicates previous infection
Table 4-11 and Fig. 4-3 describe test interpretation.

ERYTHROCYTE SEDIMENTATION RATE (ESR, sed rate, sedimentation rate)

Normal range:
Male: 0-15 mm/hr
Female: 0-20 mm/hr
Elevated in: Collagen vascular diseases, infections, myocardial infarction, neoplasms, inflammatory states (acute phase reactant), hyperthyroidism, hypothyroidism, rouleaux formation
Decreased in: Sickle cell disease, polycythemia, corticosteroids, spherocytosis, anisocytosis, hypofibrinogenemia, increased serum viscosity

ERYTHROPOIETIN (EP)

Normal: 3.7-16.0 IU/L by radioimmunoassay
Erythropoietin is a glycoprotein secreted by the kidneys that stimulates RBC production by acting on erythroid-committed stem cells.
Increased in:
Extremely high: Generally seen in patients with severe anemia (Hct <25, <7) such as in cases of aplastic anemia, severe hemolytic anemia, hematologic cancers
Very high: Patients with mild to moderate anemia (Hct, 25-35; Hb, 7-10)
High: Patients with mild anemia (e.g., AIDS, myelodysplasia)
Erythropoietin can be inappropriately elevated in patients with malignant neoplasms, renal cysts, postrenal transplant, meningioma, hemangioblastoma, and leiomyoma.
Decreased in: Renal failure, polycythemia vera, autonomic neuropathy

ESTRADIOL (serum)

Normal range:
Female, premenopausal: 30-400 pg/ml, depending on phase of menstrual cycle
Female, postmenopausal: 0-30 pg/ml
Male, adult: 10-50 pg/ml
Decreased in: Ovarian failure
Elevated in: Tumors of ovary, testis, adrenal, or nonendocrine sites (rare)

TABLE 4-11 Antibody Tests in Epstein-Barr Viral Infection

	Appearance	Peak	Disappears
Heterophil Ab	3-5 days after onset of Sx (range, 0-21 days)	During second wk after onset of Sx (1-4 wk)	2-3 mo after onset of Sx (still found at 1 yr in 20% of cases)
VCA-IgM	Beginning of Sx (1 wk before to 1 wk after Sx begin)	During first wk after onset of Sx (0-21 days)	2-3 mo after onset of Sx (1-6 mo)
VCA-IgG	3 days after onset of Sx (0-2 wk)	During second wk after onset of Sx (1-3 wk)	Decline to lower level, then persists for life
EBNA-IgG	3 wk after onset of Sx (1-4 wk)	8 mo after appearance (3-12 mo)	Lifelong
EA-D	5 days after onset of Sx (during first 1-2 wk after onset of Sx)	14-21 days after onset of Sx (1-4 wk)	9 wk after appearance (2-6 mo)
EBNA-IgM	Same as VCA-IgM	Same as VCA-IgM	Same as VCA-IgM

Reprinted from Ravel R: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.
Ab, Antibody; *EA,* early antigen; *EBNA,* Epstein-Barr virus nuclear antigen; *Sx,* symptoms; *VCA,* viral capsid antigen.

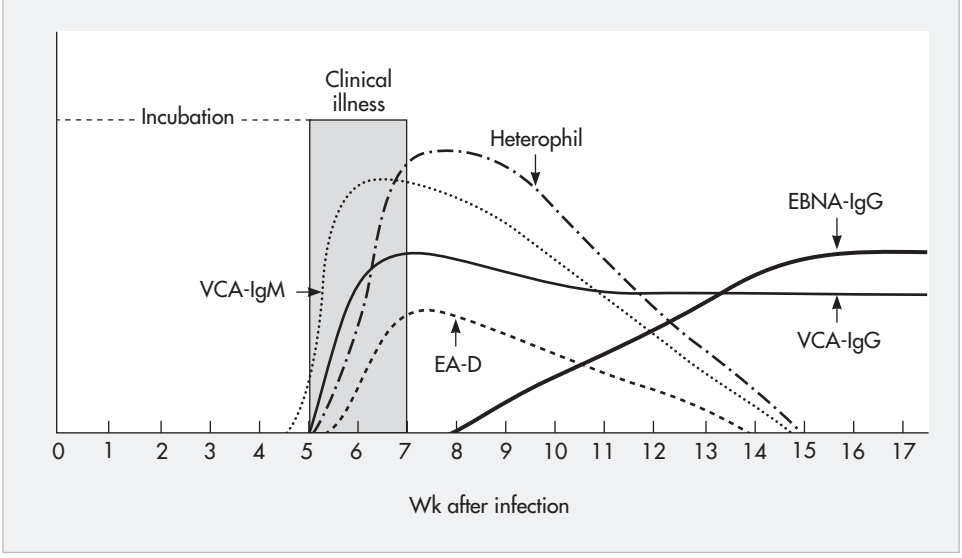

FIGURE 4-3 Tests in Epstein-Barr viral infection. See Table 4-11 for abbreviations. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

ESTROGEN

Normal range (serum):

Males:	20-80 pg/ml
Females:	
Follicular:	60-200 pg/ml
Luteal:	160-400 pg/ml
Postmenopausal:	<130 pg/ml

Normal range (urine):

Males:	4-23 μg/g creatinine
Females:	
Follicular:	7-65 μg/g creatinine
Midcycle:	32-104 μg/g creatinine
Luteal:	8-135 μg/g creatinine

Elevated in: Hyperplasia of adrenal cortex, ovarian tumors producing estrogen, granulosa and thecal cell tumors, testicular tumors

Decreased in: Menopause, hypopituitarism, primary ovarian malfunction, anorexia nervosa, hypofunction of adrenal cortex, ovarian agenesis, psychogenic stress, gonadotropin-releasing hormone deficiency

ETHANOL (blood)

Normal range:

Negative (values <10 mg/dl are considered negative)

Ethanol is metabolized at 10-25 mg/dl/hour. Levels ≥80 mg/dl are considered evidence of impairment for driving. Fatal blood concentration is considered to be >400 mg/dl.

EXTRACTABLE NUCLEAR ANTIGEN (ENA complex, anti-RNP antibody, anti-SM, anti-Smith)

Normal: Negative

Present in: Systemic lupus erythematosus, rheumatoid arthritis, Sjögren's syndrome, mixed connective tissue disease

ESTROGEN

Normal range (serum):

Males:	20-80 pg/ml
Females:	
Follicular:	60-200 pg/ml
Luteal:	160-400 pg/ml
Postmenopausal:	<130 pg/ml

Normal range (urine):

Males:	4-23 μg/g creatinine
Females:	
Follicular:	7-65 μg/g creatinine
Midcycle:	32-104 μg/g creatinine
Luteal:	8-135 μg/g creatinine

Elevated in: Hyperplasia of adrenal cortex, ovarian tumors producing estrogen, granulosa and thecal cell tumors, testicular tumors
Decreased in: Menopause, hypopituitarism, primary ovarian malfunction, anorexia nervosa, hypofunction of adrenal cortex, ovarian agenesis, psychogenic stress, gonadotropin-releasing hormone deficiency

ETHANOL (blood)

Normal range:
Negative (values <10 mg/dl are considered negative)
Ethanol is metabolized at 10-25 mg/dl/hour. Levels ≥80 mg/dl are considered evidence of impairment for driving. Fatal blood concentration is considered to be >400 mg/dl.

EXTRACTABLE NUCLEAR ANTIGEN (ENA complex, anti-RNP antibody, anti-SM, anti-Smith)

Normal: Negative
Present in: Systemic lupus erythematosus, rheumatoid arthritis, Sjögren's syndrome, mixed connective tissue disease

FACTOR V LEIDEN

Test description: PCR test performed on whole blood or tissue. This single mutation, found in 2%-8% of the general Caucasian population, is the single most common cause of hereditary thrombophilia.

FASTING BLOOD SUGAR

See GLUCOSE, FASTING

FBS

See GLUCOSE, FASTING

FDP

See FIBRIN DEGRADATION PRODUCT

FECAL FAT, QUANTITATIVE (72-hr collection)

Normal range: 2-6 g/24 hr (7-21 mmol/dl [CF: 3.515; SMI: 1 mmol/dl])
Elevated in: Malabsorption syndrome

FECAL GLOBIN IMMUNOCHEMICAL TEST

Normal: Negative. This test is performed by immunochromatography on a cellulose strip that has been impregnated with various antibodies. The test uses a small amount of toilet water as the specimen and is placed onto absorbent pads of card similar to traditional OB card. There is no direct handling of stool. This test is specific for the globin portion of the hemoglobin molecule, which confers lower GI bleeding specificity. It specifically detects blood from the lower GI tract; guaic tests are not lower GI specific. It is more sensitive than typical Hemoccult test (detection limit 50 mcg Hb/g feces versus >500 mcg Hb/g feces for Hemoccult). It has no dietary restrictions and gives no false-positives due to plant peroxidases and red meats. It has no medication restrictions. Iron supplements and NSAIDs do not cause false-positives. Vitamin C does not cause false-negatives.
Positive in: Lower GI bleeding

FERRITIN (serum)

Normal range: 18-300 ng/ml (18-300 μg/L [CF: 1; SMI: 10 μg/L])
Elevated in: Hyperthyroidism, inflammatory states, liver disease (ferritin elevated from necrotic hepatocytes), neoplasms (neuroblastomas, lymphomas, leukemia, breast carcinoma), iron replacement therapy, hemochromatosis, hemosiderosis
Decreased in: Iron deficiency anemia

α-1 FETOPROTEIN

Normal range: 0-20 ng/ml (0-20 μg/L [CF: 1; SMI: 1 μg/L])
Elevated in: Hepatocellular carcinoma (usually values >1000 ng/ml), germinal neoplasms (testis, ovary, mediastinum, retroperitoneum), liver disease (alcoholic cirrhosis, acute hepatitis, chronic active hepatitis), fetal anencephaly, spina bifida, basal cell carcinoma, breast carcinoma, pancreatic carcinoma, gastric carcinoma, retinoblastoma, esophageal atresia

FIBRIN DEGRADATION PRODUCT (FDP)

Normal range: <10 μg/ml
Elevated in: Disseminated intravascular coagulation, primary fibrinolysis, pulmonary embolism, severe liver disease
NOTE: The presence of rheumatoid factor may cause falsely elevated FDP.

FIBRINOGEN

Normal range: 200-400 mg/dl (2-4 g/L [CF: 0.01; SMI: 0.1 g/L])
Elevated in: Tissue inflammation or damage (acute phase protein reactant), oral contraceptives, pregnancy, acute infection, myocardial infarction
Decreased in: Disseminated intravascular coagulation, hereditary afibrinogenemia, liver disease, primary or secondary fibrinolysis, cachexia

FOLATE (folic acid)

Normal range:
Plasma: 2-10 ng/ml (4-22 nmol/L [CF: 2.266; SMI: 2 nmol/L])
Red blood cells: 140-960 ng/ml (550-2200 nmol/L [CF: 2.266; SMI: 10 nmol/L])
Decreased in: Folic acid deficiency (inadequate intake, malabsorption), alcoholism, drugs (methotrexate, trimethoprim, phenytoin, oral contraceptives, Azulfidine), vitamin B_{12} deficiency (defective red cell folate absorption), hemolytic anemia
Elevated in: Folic acid therapy

FOLLICLE-STIMULATING HORMONE (FSH)

Normal range: 5-20 mIU/ml
Elevated in: Menopause, primary gonadal failure, alcoholism, castration, Klinefelter's syndrome, gonadotropin-secreting pituitary hormones
Decreased in: Pregnancy, polycystic ovary disease, anorexia nervosa, anterior pituitary hypofunction

FREE T_4

See T_4, FREE

FREE THYROXINE INDEX

Normal range: 1.1-4.3
INCREASED THYROXINE OR FREE THYROXINE VALUES
Laboratory error
Primary hyperthyroidism (T_4/T_3 type)
Severe thyroxine-binding globulin elevation
Excess therapy of hypothyroidism
Excessive dose of levothyroxine
Active thyroiditis (subacute, painless, early active Hashimoto's disease)
Familial dysalbuminemic hyperthyroxinemia (some FT_4 kits, especially analog types)
Peripheral resistance to T_4 syndrome
Amiodarone or propranolol
Postpartum transient toxicosis
Factitious hyperthyroidism
Jod-Basedow (iodine-induced) hyperthyroidism
Severe nonthyroid illness
Acute psychosis (especially paranoid schizophrenia)
T_4 sample drawn 2-4 hr after levothyroxine dose
Struma ovarii
Pituitary thyroid-stimulating hormone–secreting tumor
Certain x-ray contrast media (Telepaque and Oragrafin)
Acute porphyria
Heparin effect (some T_4 and FT_4 kits)

Amphetamine, heroin, methadone, and phencyclidine abuse
Perphenazine or 5-fluorouracil
Antithyroid or anti-IgG heterophil (HAMA) autoantibodies
"T_4" hyperthyroidism
Hyperemesis gravidarum; about 50% of patients
High altitudes

DECREASED THYROXINE OR FREE THYROXINE VALUES

Laboratory error
Primary hypothyroidism
Severe nonthyroid illness*
Lithium therapy
Severe thyroxine-binding globulin decrease (congenital, disease, or drug-induced) or severe albumin decrease*
Dilantin, Depakene, or high-dose salicylate drugs*
Pituitary insufficiency
Large doses of inorganic iodide (e.g., saturated solution of potassium iodide)
Moderate or severe iodine deficiency
Cushing's syndrome
High-dose glucocorticoid drugs
Pregnancy, third trimester (low normal or small decrease)
Addison's disease; some patients (30%)
Heparin effect (a few FT_4 kits)
Desipramine or amiodarone drugs
Acute psychiatric illness

FTA-ABS (serum)

Normal: Nonreactive
Reactive in: Syphilis, other treponemal diseases (yaws, pinta, bejel), SLE, pregnancy

FUROSEMIDE STIMULATION TEST

Normal: Test is performed by giving 60 mg furosemide orally after overnight fast. Patient should be on a normal diet without medications the week before the test. Normal results: renin 1-6 ng angiotensin L/ml/hr.
Elevated in: Renovascular hypertension, Barrter's syndrome, high-renin essential hypertension, pheochromocytoma
No response in: Primary aldosteronism, low-renin essential hypertension, hyporeninemic hypoaldosteronism

Amphetamine, heroin, methadone, and phencyclidine abuse
Perphenazine or 5-fluorouracil
Antithyroid or anti-IgG heterophil (HAMA) autoantibodies
"T_4" hyperthyroidism
Hyperemesis gravidarum; about 50% of patients
High altitudes

DECREASED THYROXINE OR FREE THYROXINE VALUES

Laboratory error
Primary hypothyroidism
Severe nonthyroid illness*
Lithium therapy
Severe thyroxine-binding globulin decrease (congenital, disease, or drug-induced) or severe albumin decrease*
Dilantin, Depakene, or high-dose salicylate drugs*
Pituitary insufficiency
Large doses of inorganic iodide (e.g., saturated solution of potassium iodide)
Moderate or severe iodine deficiency
Cushing's syndrome
High-dose glucocorticoid drugs
Pregnancy, third trimester (low normal or small decrease)
Addison's disease; some patients (30%)
Heparin effect (a few FT_4 kits)
Desipramine or amiodarone drugs
Acute psychiatric illness

FTA-ABS (serum)

Normal: Nonreactive
Reactive in: Syphilis, other treponemal diseases (yaws, pinta, bejel), SLE, pregnancy

FUROSEMIDE STIMULATION TEST

Normal: Test is performed by giving 60 mg furosemide orally after overnight fast. Patient should be on a normal diet without medications the week before the test. Normal results: renin 1-6 ng angiotensin L/ml/hr.
Elevated in: Renovascular hypertension, Barrter's syndrome, high-renin essential hypertension, pheochromocytoma
No response in: Primary aldosteronism, low-renin essential hypertension, hyporeninemic hypoaldosteronism

GAMMA-GLUTAMYL TRANSFERASE (gGt)

See γ-GLUTAMYL TRANSFERASE

GASTRIN (serum)

Normal range: 0-180 pg/ml (0-180 ng/L [CF: 1; SMI: 10 ng/L])
Elevated in: Zollinger-Ellison syndrome (gastrinoma), pernicious anemia, hyperparathyroidism, retained gastric antrum, chronic renal failure, gastric ulcer, chronic atrophic gastritis, pyloric obstruction, malignant neoplasms of the stomach, H_2-blockers, omeprazole, calcium therapy, ulcerative colitis, rheumatoid arthritis

GASTRIN STIMULATION TEST

Normal: Gastrin stimulation test after calcium infusion is performed by giving a calcium infusion (15 mg Ca/Kg in 500 ml normal saline over 4 hours). Serum is drawn in fasting state before infusion and at 1, 2, 3, and 4 hr. Normal response is little or no increase over baseline gastrin level.
Elevated in: Gastrinoma (gastrin >400 pg/ml), duodenal ulcer (gastrin level increase <400 ng/L)
Decreased in: Pernicious anemia, atrophic gastritis

GLIADIN ANTIBODIES, IgA AND IgG

Normal: <25 U, equivocal 20-25 U, positive >25 U. Test is useful to monitor compliance with gluten-free diet in patients with celiac disease.
Elevated in: Celiac disease with dietary noncompliance

GLOMERULAR BASEMENT MEMBRANE (gBm) ANTIBODY

Normal: Negative
Present in: Goodpasture's syndrome

GLOMERULAR FILTRATION RATE

Normal:

Ages 20-29	116 ml/min/1.73 m^2
Ages 30-39	107 ml/min/1.73 m^2
Ages 40-49	99 ml/min/1.73 m^2
Ages 50-59	93 ml/min/1.73 m^2
Ages 60-69	85 ml/min/1.73 m^2
Ages >75	75 ml/min/1.73 m^2

Decreased in: Renal insufficiency, decreased renal blood flow

GLUCAGON

Normal: 20-100 pg/ml
Elevated in: Glucagonoma (900-7800 pg/ml), chronic renal failure, diabetes mellitus, glucocorticoids, insulin, nifedipine, danazol, sympathomimetic amines
Decreased in: Hyperlipoproteinemia (types III, IV), beta-blockers, secretin

GLUCOSE, FASTING (FBS, Fasting Blood Sugar)

Normal range: 60-99 mg/dl (3.8-6.0 mmol/L [CF: 0.05551; SMI: 0.1 mmol/L])
Elevated in: Diabetes mellitus, stress, infections, myocardial infarction, cerebrovascular accident, Cushing's syndrome, acromegaly, acute pancreatitis, glucagonoma, hemochromatosis, drugs (glucocorticoids, diuretics [thiazides, loop diuretics]), glucose intolerance, impaired fasting glucose
Decreased in: Sulfonylurea therapy, insulin therapy, reactive hypoglycemia (e.g., s/b subtotal gastrectomy), starvation, insulinoma, glycogen storage disorders, severe liver disease or renal disease, ethanol-induced hypoglycemia, mesenchymal tumors that secrete insulin-like hormones

GLUCOSE, POSTPRANDIAL

Normal range: <140 mg/dl (<7.8 mmol/L [CF: 0.05551; SMI: 0.1 mmol/L])
Elevated in: Diabetes mellitus, glucose intolerance
Decreased in: Post–gastrointestinal resection, reactive hypoglycemia, hereditary fructose intolerance, galactosemia, leucine sensitivity

GLUCOSE TOLERANCE TEST

Normal values above fasting:
30 min: 30-60 mg/dl (1.65-3.3 mmol/L [CF: 0.05551; SMI: 0.1 mmol/L])
60 min: 20-50 mg/dl (1.1-2.75 mmol/L [CF: 0.05551; SMI: 0.1 mmol/L])
120 min: 5-15 mg/dl (0.28-0.83 mmol/L [CF: 0.05551; SMI: 0.1 mmol/L])
180 min: fasting level or below
Abnormal in: Glucose intolerance, diabetes mellitus, Cushing's syndrome, acromegaly, pheochromocytoma, gestational diabetes

GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) SCREEN (blood)

Normal: G6PD enzyme activity detected
Abnormal: If a deficiency is detected, quantitation of G6PD is necessary; a G6PD screen may be falsely interpreted as "normal" after an episode of hemolysis because most G6PD-deficient cells have been destroyed.

γ-GLUTAMYL TRANSFERASE (GGT)

Normal range: 0-30 U/L (0.050 μkat/L [CF: 0.01667; SMI: 0.01 μkat/L])
Elevated in: Chronic alcoholic liver disease, neoplasms (hepatoma, metastatic disease to the liver, carcinoma of the pancreas), systemic lupus erythematosus, congestive heart failure, trauma, nephrotic syndrome, sepsis, cholestasis, drugs (phenytoin, barbiturates)

GLYCATED (glycosylated) HEMOGLOBIN (HbA_{1c}) (glycohemoglobin)

Normal range: 4.0%-5.9%
Elevated in: Uncontrolled diabetes mellitus (glycated hemoglobin levels reflect the level of glucose control over the preceding 120 days), lead toxicity, alcoholism, iron deficiency anemia, hypertriglyceridemia
Decreased in: Hemolytic anemias, decreased red blood cell survival, pregnancy, acute or chronic blood loss, chronic renal failure, insulinoma, congenital spherocytosis, hemoglobin S, C, and D diseases

GROWTH HORMONE

Normal: Male: 1-9 ng/ml; female: 1-16 ng/ml
Elevated in: Pituitary gigantism, acromegaly, ectopic GH secretion, cirrhosis, renal failure, anorexia nervosa, stress, exercise, prolonged fasting, amphetamines, beta-blockers, insulin, levodopa, metoclopramide, clonidine, vasopressin, human growth hormone (HGH) supplementation
Decreased in: Hypopituitarism, pituitary dwarfism, adrenocortical hyperfunction, bromocriptine, corticosteroids, glucose

GROWTH HORMONE RELEASING HORMONE (GHRH)

Normal: $<$50 pg/ml
Elevated in: Acromegaly caused by GHRH secretion by neoplasms

GROWTH HORMONE SUPPRESSION TEST

(after glucose)

Normal: Test is done by giving 1.75 g glucose/kg orally after overnight fast. Blood is drawn at baseline, after 60 min, and after 120 min of glucose load. Normal response is growth hormone suppression to $<$2 ng/ml or undetectable levels.
Abnormal: There is no or incomplete suppression from the high basal level in gigantism or acromegaly.

GROWTH HORMONE

Normal: Male: 1-9 ng/ml; female: 1-16 ng/ml
Elevated in: Pituitary gigantism, acromegaly, ectopic GH secretion, cirrhosis, renal failure, anorexia nervosa, stress, exercise, prolonged fasting, amphetamines, beta-blockers, insulin, levodopa, metoclopramide, clonidine, vasopressin, human growth hormone (HGH) supplementation
Decreased in: Hypopituitarism, pituitary dwarfism, adrenocortical hyperfunction, bromocriptine, corticosteroids, glucose

GROWTH HORMONE RELEASING HORMONE (GHRH)

Normal: <50 pg/ml
Elevated in: Acromegaly caused by GHRH secretion by neoplasms

GROWTH HORMONE SUPPRESSION TEST (after glucose)

Normal: Test is done by giving 1.75 g glucose/kg orally after overnight fast. Blood is drawn at baseline, after 60 min, and after 120 min of glucose load. Normal response is growth hormone suppression to <2 ng/ml or undetectable levels.
Abnormal: There is no or incomplete suppression from the high basal level in gigantism or acromegaly.

HAM TEST (acid serum test)

Normal: Negative
Positive in: Paroxysmal nocturnal hemoglobinuria
False-positive in: Hereditary or acquired spherocytosis, recent transfusion with aged red blood cells, aplastic anemia, myeloproliferative syndromes, leukemia, hereditary dyserythropoietic anemia type II

HAPTOGLOBIN (serum)

Normal range: 50-220 mg/dl (0.50-2.2 g/L [CF: 0.01; SMI: 0.01 g/L])
Elevated in: Inflammation (acute phase reactant), collagen vascular diseases, infections (acute phase reactant), drugs (androgens), obstructive liver disease
Decreased in: Hemolysis (intravascular more than extravascular), megaloblastic anemia, severe liver disease, large tissue hematomas, infectious mononucleosis, drugs (oral contraceptives)

HBA_{1c}

See GLYCATED HEMOGLOBIN

HDL

See HIGH-DENSITY LIPOPROTEIN CHOLESTEROL

HELICOBACTER PYLORI (serology, stool antigen)

Normal range: Not detected
Detected in: *H. pylori* infection. Positive serology can indicate current or past infection. Positive stool antigen test indicates acute infection (sensitivity and specificity >90%). Stool testing should be delayed at least 4 weeks after eradication therapy.

HEMATOCRIT

Normal range:
Male: 39%-49% (0.39-0.49 [CF: 0.01; SMI: 0.01])
Female: 33%-43% (0.33-0.43 [CF: 0.01; SMI: 0.01])
Elevated in: Polycythemia vera, smoking, chronic obstructive pulmonary disease, high altitudes, dehydration, hypovolemia
Decreased in: Blood loss (gastrointestinal, genitourinary) anemia

HEMOGLOBIN

Normal range:
Male: 13.6-17.7 g/dl (136-172 g/L [CF: 10; SMI: 1 g/L])
Female: 12.0-15.0 g/dl (120-150 g/L [CF: 10; SMI: 1 g/L])
Elevated in: Hemoconcentration, dehydration, polycythemia vera, chronic obstructive pulmonary disease, high altitudes, false elevations (hyperlipemic plasma, white blood cells >50,000/mm^3), stress
Decreased in: Hemorrhagic (gastrointestinal, genitourinary) anemia

$HEMOGLOBIN\ A_{1c}$

See GLYCATED HEMOGLOBIN

HEMOGLOBIN ELECTROPHORESIS

Normal range:
HbA_1: 95%-98%
HbA_2: 1.5%-3.5%
HbF: <2%
HbC: absent
HbS: absent

HEMOGLOBIN, GLYCATED

See GLYCATED HEMOGLOBIN

HEMOGLOBIN, GLYCOSYLATED

See GLYCATED HEMOGLOBIN

HEMOGLOBIN H

Normal: Negative
Present in: Hemoglobin H disease, alpha-thalassemia trait, unstable hemoglobin disorders

HEMOGLOBIN, URINE

See URINE HEMOGLOBIN

HEMOSIDERIN, URINE

See URINE HEMOGLOBIN

HEPARIN-INDUCED THROMBOCYTOPENIA ANTIBODIES

Normal: Antigen assay: Negative, <0.45; weak, 0.45-1.0; strong, >1.0
Elevated in: Heparin-induced thrombocytopenia

HEPATITIS A ANTIBODY

Normal: Negative
Present in: Viral hepatitis A; can be IgM or IgG (if IgM, acute hepatitis A; if IgG, previous infection with hepatitis A)
See Fig. 4-4 for serologic tests in HAV infection.

HAV-IgM ANTIBODY

Appearance: About the same time as clinical symptoms (3-4 weeks after exposure, range 14-60 days), or just before beginning of AST/ALT elevation (range 10 days before to 7 days after)
Peak: About 3-4 weeks after onset of symptoms (1-6 weeks)
Becomes nondetectable: 3-4 months after onset of symptoms (1-6 months). In a few cases HAV-IgM antibody can persist as long as 12-14 months.

HAV TOTAL ANTIBODY

Appearance: About 3 weeks after IgM becomes detectable (therefore about the middle of clinical symptom period to early convalescence)
Peak: About 1-2 months after onset
Becomes nondetectable: Remains elevated for life but can somewhat slowly fall

HEPATITIS A VIRAL INFECTION

Best all-purpose test(s) to diagnose acute HAV infection = HAV-Ab (IgM)
Best all-purpose test(s) to demonstrate past HAV infection/immunity = HAV-Ab (total)

HEPATITIS B SURFACE ANTIGEN (HBsAg)

Normal: Not detected
Detected in: Acute viral hepatitis type B, chronic hepatitis B
Appearance: 2-6 weeks after exposure (range, 6 days to 6 months); 5%-15% of patients are negative at onset of jaundice
Peak: 1-2 weeks before to 1-2 weeks after onset of symptoms
Becomes nondetectable: 1-3 months after peak (range, 1 week to 5 months)

HEPATITIS B VIRAL INFECTION

Figs. 4-5, 4-6, and 4-7 illustrate antigens and antibodies in hepatitis B infection.

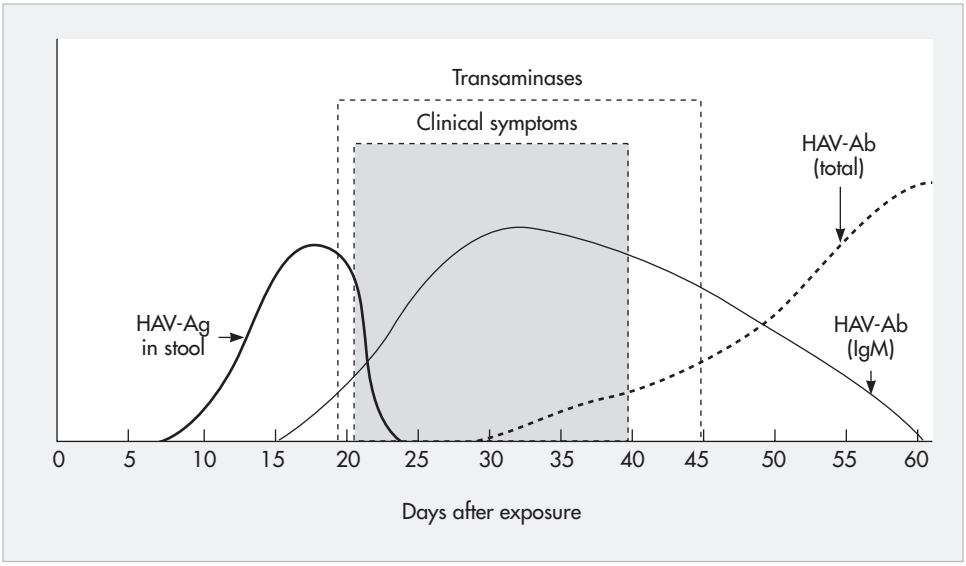

FIGURE 4-4 Serologic tests in HAV infection. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

HB_S
-Ag
HB_SAg: shows current active HBV infection.
Persistence over 6 months indicates carrier/chronic HBV infection.
HBV nucleic acid probe: present before and longer than HB_SAg.
More reliable marker for increased infectivity than HB_SAg and/or HB_eAg.
-Ab
HB_SAb-total: shows previous healed HBV infection and evidence of immunity.

HB_C
-Ab
HB_CAb-IgM: shows either acute or very recent infection by HBV.
In convalescent phase of acute HBV, may be elevated when HB_SAg has disappeared (core window).
Negative HB_CAb-IgM with positive HB_SAg suggests either very early acute HBV or carrier/chronic HBV.
HB_CAb-total: only useful to show past HBV infection if HB_SAg and HB_cAb-IgM are both negative.

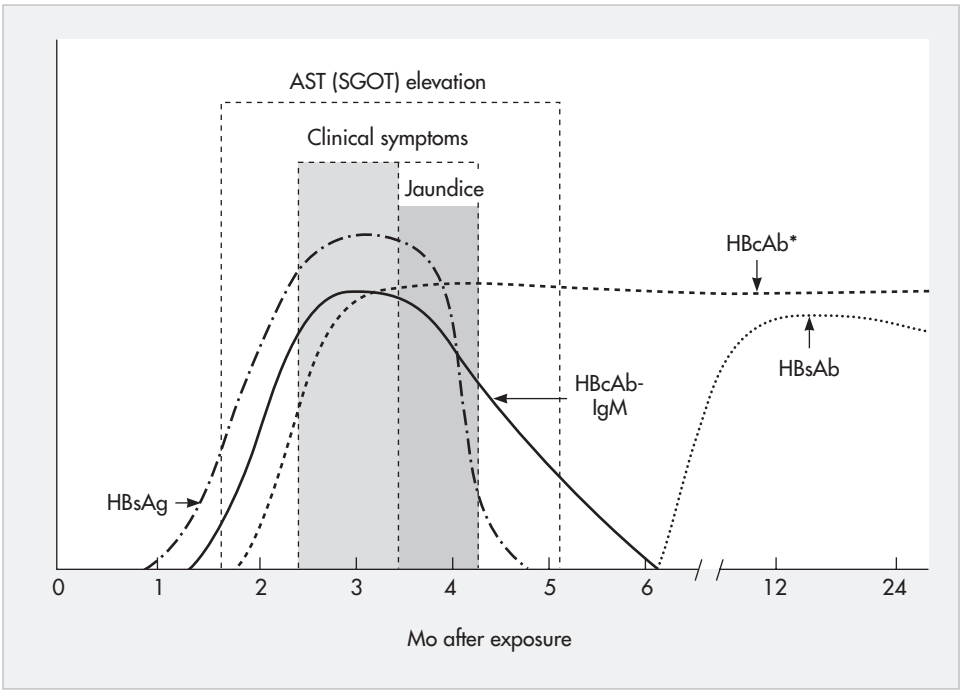

FIGURE 4-5 HBV surface antigen-antibody and core antibodies. Note "core window." *HB_CAb = HB_CAb-IgM + HBCAb-IgG (combined). (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

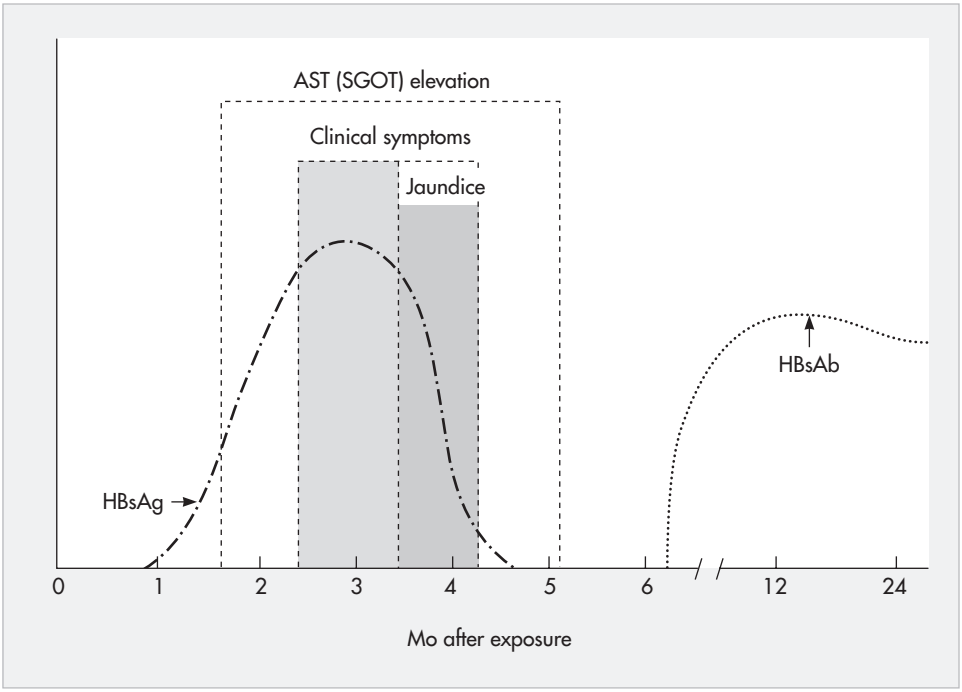

FIGURE 4-6 HBV surface antigen and antibody (HB_SAg and HB_SAb-total). (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

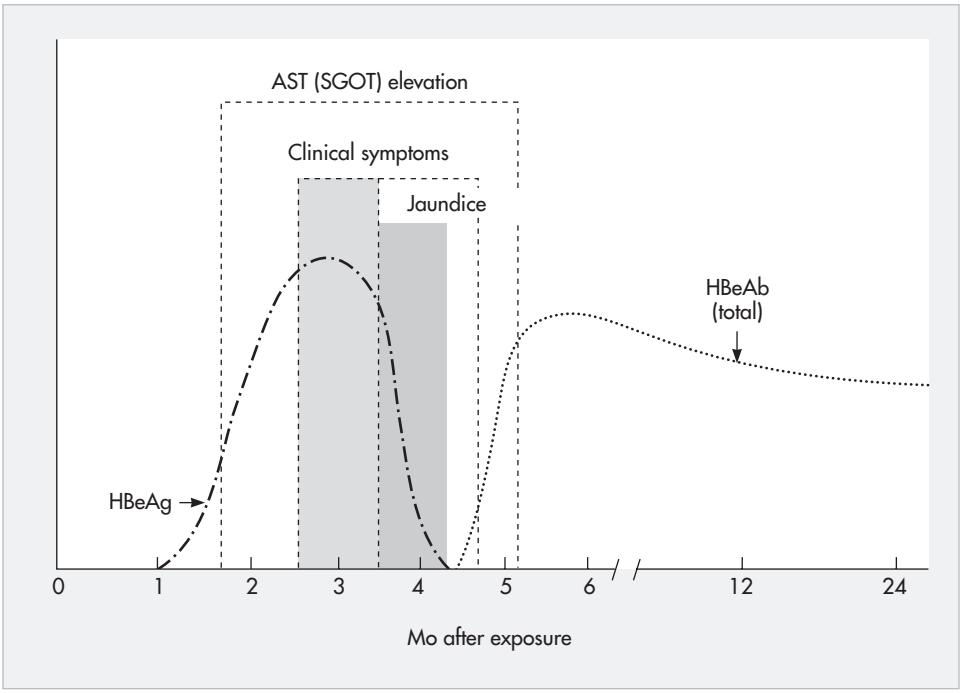

FIGURE 4-7 HBVe antigen and antibody. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

HB_e
-Ag

HB_e-AbAg: when present, especially without HB_eAb, suggests increased patient infectivity.

HB_eAb-total: when present, suggests less patient infectivity.

I. HB_SAg positive, HB_CAb negative*
   About 5% (range, 0%-17%) of patients with early-stage HBV acute infection (HB_CAb rises later)

II. HB_SAg positive, HB_CAb positive, HB_SAb negative
   a. Most of the clinical symptom stage
   b. Chronic HBV carriers without evidence of liver disease ("asymptomatic carriers")
   c. Chronic HBV hepatitis (chronic persistent type or chronic active type)

III. HB_SAg negative, HB_CAb positive,* HB_SAb negative
   a. Late clinical symptom stage or early convalescence stage (core window)

b. Chronic HBV infection with HB_SAg below detection levels with current tests
c. Old previous HBV infection

IV. HB_SAg negative, HB_CAb positive, HB_SAb positive
a. Late convalescence to complete recovery
b. Old infection

HEPATITIS C VIRAL INFECTION

Fig. 4-8 illustrates antigens and antibodies in hepatitis C infection.

HEPATITIS C RNA

Normal: Negative
Elevated in: Hepatitis C. Detection of hepatitis C-RNA is used to confirm current infection and to monitor treatment. Quantitative assays (viral load) are needed before treatment to assess response (<2 log decrease after 12-week treatment indicates lack of response).

HCV
-Ag
HCV nucleic acid probe: shows current infection by HCV (especially with PCR amplification).
-Ab
HCV-Ab (IgG): current, convalescent, or old HCV infection.

HAV
-Ag
HAV-Ag by EM: shows presence of virus in stool early in infection.
-Ab
HAV-Ab (IgM): current or recent HAV infection.
HAV-Ab (total): convalescent or old HAV infection.

HEPATITIS D VIRAL INFECTION

Fig. 4-9 illustrates antigens and antibodies in hepatitis D infection.
Best current all-purpose screening test = ADV-Ab (total)
Best test to differentiate acute from chronic infection = HDV-Ab (IgM)

DELTA HEPATITIS COINFECTION (acute HDV1 acute HBV) OR SUPERINFECTION (acute HDV1 chronic HBV)

HDV
-Ag
HDV-Ag: shows current infection (acute or chronic) by HDV.
HDV nucleic acid probe: detects antigen before and longer than HDV-Ag by EIA.
-Ab
HDV-Ab (IgM): high elevation in acute HDV; does not persist.
Low or moderate elevation in convalescent HDV; does not persist.
Low to high persistent elevation in chronic HDV (depends on degree of cell injury and sensitivity of the assay).
HDV-Ab (total): high elevation in acute HDV; does not persist.
High persistent elevation in chronic HDV.

HDV-AG

Detected by DNA probe, less often by immunoassay
Appearance: Prodromal stage (before symptoms); just at or after initial rise in ALT (about a week after appearance of HB_SAg and about the time HB_CAb-IgM level begins to rise)
Peak: 2-3 days after onset
Becomes nondetectable: 1-4 days (may persist until shortly after symptoms appear)

HDV-AB (IgM)

Appearance: About 10 days after symptoms begin (range, 1-28 days)
Peak: About 2 weeks after first detection
Becomes nondetectable: About 35 days (range, 10-80 days) after first detection (most other IgM antibodies take 3-6 months to become nondetectable)

HDV-AB (total)

Appearance: About 50 days after symptoms begin (range, 14-80 days); about 5 weeks after HDV-Ag (range, 3-11 weeks)
Peak: About 2 weeks after first detection
Becomes nondetectable: About 7 months after first detection (range, 4-14 months)

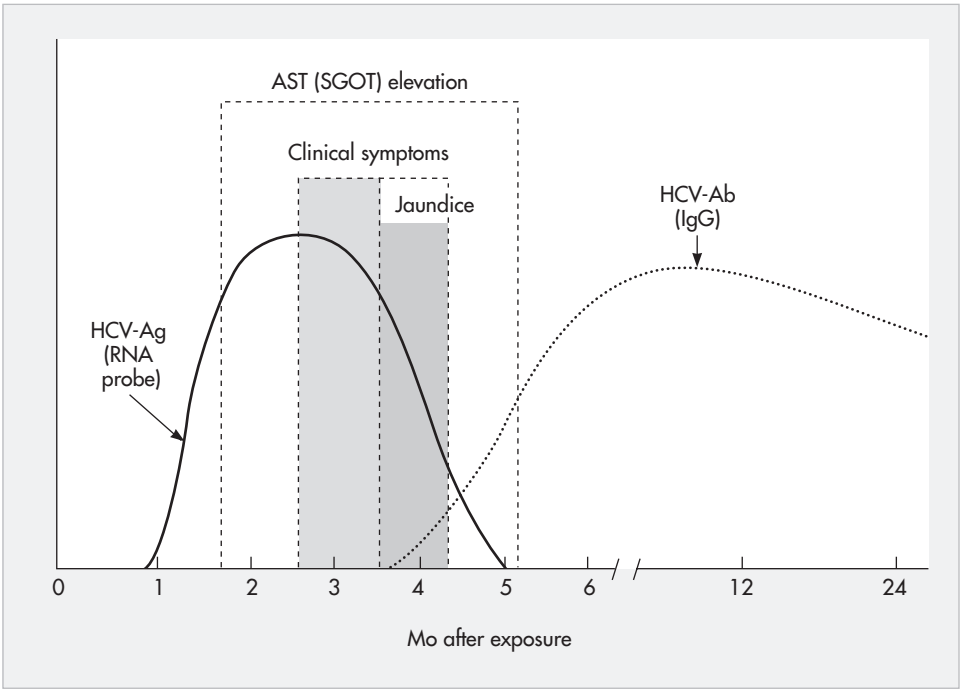

FIGURE 4-8 HCV antigen and antibody. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

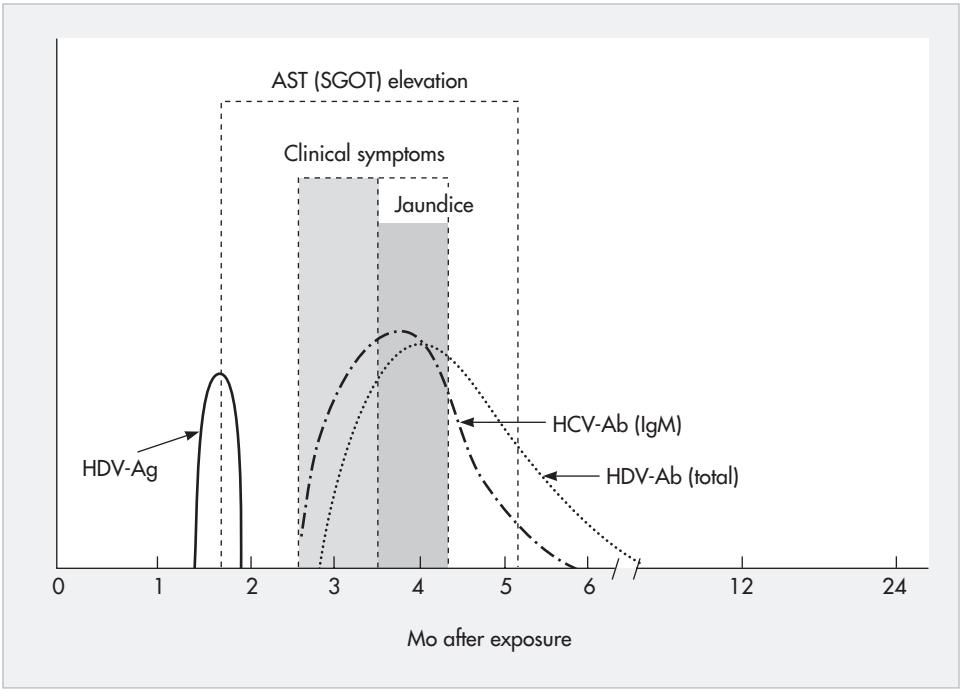

FIGURE 4-9 HDV antigen and antibodies. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

HER-2/*NEU*

Normal: Negative
Present in: Present in 25%-30% of primary breast cancers. It can also be found in other epithelial tumors, including lung, hepatocellular, pancreatic, colon, stomach, ovarian, cervical, and bladder cancer. Trastuzumab (Herceptin) is a humanized monoclonal antibody against Her-2/*neu*. This test is useful to identify patients with metastatic; recurrent; and/or treatment refractory, unresectable, locally advanced breast cancer for trastuzumab treatment.

HERPES SIMPLEX VIRUS (HSV)

Test description: The PCR test can be performed on serum biopsy samples, CSF, vitreous humor.

Table 2-3 describes laboratory diagnosis of herpes virus infections.

HFE SCREEN FOR HEREDITARY HEMOCHROMATOSIS

Test description: PCR test can be performed on whole blood or tissue. One mutation (C282Y) and two polymorphisms (H63D, S65C) account for the majority of alleles associated with this disease.

HETEROPHIL ANTIBODY

Normal: Negative
Positive in: Infectious mononucleosis

HIGH-DENSITY LIPOPROTEIN (HDL) CHOLESTEROL

Normal range:
Male: 40-70 mg/dl (0.8-1.8 mmol/L [CF: 0.02586; SMI: 0.05 mmol/L])
Female: 50-90 mg/dl (1.1-2.35 mmol/L [CF: 0.02586; SMI: 0.05 mmol/L])
Increased in: Use of gemfibrozil, statins, fenofibrate, nicotinic acid, estrogens, regular aerobic exercise, small (1 oz) daily alcohol intake
Decreased in: Deficiency of apoproteins, liver disease, probucol ingestion, Tangier disease

NOTE: A cholesterol/HDL ratio >4.0 is associated with increased risk of coronary artery disease.

HLA ANTIGENS

Associated disorders: see Table 4-12.

HOMOCYSTEINE (plasma)

Normal range:
0-30 years: 4.6-8.1 mcmol/L
30-59 years: 6.3-11.2 mcmol/L (males), 4-5-7.9 mcmol/L (females)
>59 years: 5.8-11.9 mcmol/L
Increased: Thrombophilic states, B_6, B_{12}, folic acid, riboflavin deficiency, pregnancy, homocystinuria

NOTE: An increased homocysteine level is an independent risk factor for atherosclerosis.

TABLE 4-12 HLA Antigens Associated with Specific Diseases

Antigen	Condition	Antigen	Condition
HLA-B27	Ankylosing spondylitis	HLA-B8, Dw3	Celiac disease
Reiter's syndrome	HLA-B8, Dw3	Dermatitis herpetiformis	
Psoriatic arthritis	HLA-B8	Myasthenia gravis	
HLA-A10, B18, Dw2	C2 deficiency	HLA-B8	Chronic active hepatitis in children
HLA-A2, B40, Cw3	C4 deficiency	HLA-Drw4	Active chronic hepatitis in adults
HLA-B7, Dw2	Multiple sclerosis	HLA-B13, Bw17	Psoriasis
HLA-A3	Hemochromatosis		

Reprinted from Cerra FB: *Manual of critical care,* St Louis, 1987, Mosby.
HLA, Human leukocyte antigen.

HUMAN HERPES VIRUS 8 (HHV8)

Test description: PCR test can be performed on whole blood, tissue, bone marrow, and urine. HHV8 is found in all forms of Kaposi's sarcoma.

HUMAN CHORIONIC GONADOTROPIN (hCG)

Normal range: Varies with gestational stage:

1 wk:	5-50 mU/ml
1-2 wk:	50-550 mU/ml
2-3 wk:	up to 5000 mU/ml
3-4 wk:	up to 10,000 mU/ml
4-5 wk:	up to 50,000 mU/ml
2-3 mo:	10,000-100,000 mU/ml

Elevated in: Normal pregnancy, hydatidiform mole, choriocarcinoma, germ cell tumors of testicle, some nontrophoblastic neoplasms (e.g., neoplasms of cervix, gastrointestinal tract, ovary, lung, breast)

HUMAN IMMUNODEFICIENCY VIRUS ANTIBODY, TYPE 1 (HIV-1)

Normal range: Not detected

Abnormal result: HIV antibodies usually appear in the blood 1-4 months after infection.

Testing sequence:

1. ELISA is the recommended initial screening test. Sensitivity and specificity are >99%. False-positive ELISA may occur with autoimmune disorders, administration of immune globulin manufactured before 1985, within 6 weeks of testing, in the presence of rheumatoid factor, in the presence of DLA-DR antibodies in multigravida female, with administration of influenza vaccine within 3 months of testing, with hemodialysis, with positive plasma reagin test, and with certain medical disorders (hemophilia, hypergammaglobulinemia, alcoholic hepatitis).
2. A positive ELISA is confirmed with Western blot. False-positive Western blot may result from connective tissue disorders, human leukocyte antigen antibodies, polyclonal gammopathies, hyperbilirubinemia, presence of antibody to another human retrovirus, or cross-reaction with other non-virus-derived proteins in healthy persons. Undetermined Western blot may occur in AIDS patients with advanced immunodeficiency (caused by loss of antibodies) and in recent HIV infections.
3. PCR is used to confirm indeterminate Western blot results or negative results in persons with suspected HIV infection.

Fig. 4-10 describes tests in HIV infection; indications for plasma HIV RNA testing are described in Table 4-13.

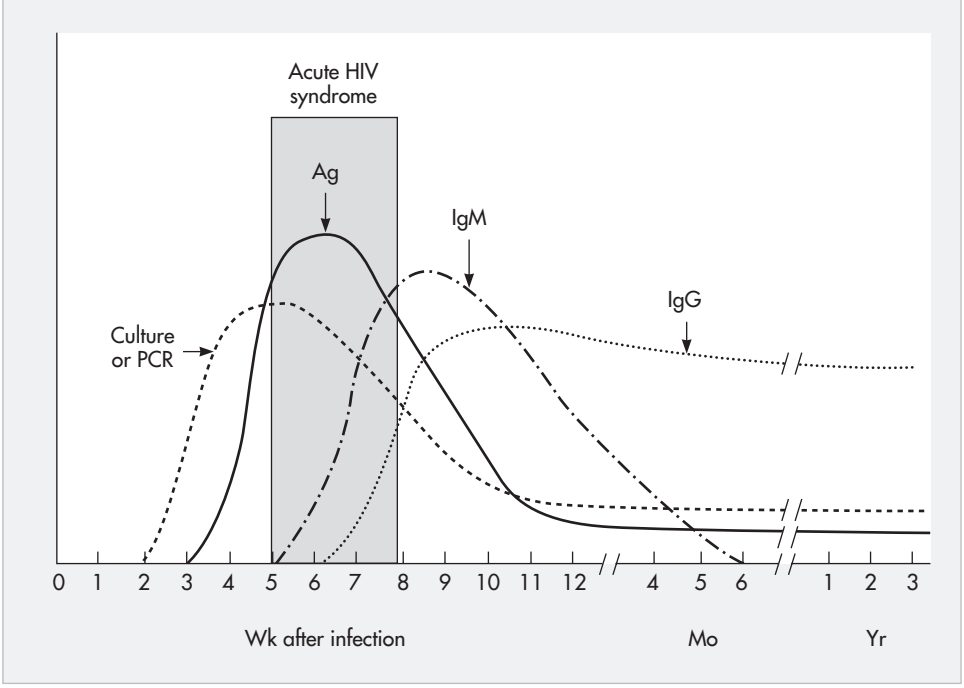

FIGURE 4-10 Tests in HIV-1 infection. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

TABLE 4-13 Indications for Plasma HIV RNA Testing*

Clinical Indication	Information	Use
Syndrome consistent with acute HIV infection	Establishes diagnosis when HIV antibody test is negative or indeterminate	Diagnosis†
Initial evaluation of newly diagnosed HIV infection	Baseline viral load set point	Decision to start or defer therapy
Every 3-4 mo in patients not on therapy	Changes in viral load	Decision to start therapy
4-8 wk after initiation of antiretroviral therapy	Initial assessment of drug efficacy	Decision to continue or change therapy
3-4 mo after start of therapy	Maximal effect of therapy	Decision to continue or change therapy
Every 3-4 mo in patients on therapy	Durability of antiretroviral effect	Decision to continue or change therapy
Clinical event or significant decline in CD4+ T cells	Association with changing or stable	Decision to continue, initiate, or change

Reprinted from *MMWR,* 47:RR-5, 1998.

*Acute illness (e.g., bacterial pneumonia, tuberculosis, HSV, PCP) and immunizations can cause increase in plasma HIV RNA for 2-4 wk; viral load testing should not be performed during this time. Plasma HIV RNA results should usually be verified with a repeat determination before starting or making changes in therapy. HIV RNA should be measured using the same laboratory and the same assay.

†Diagnosis of HIV infection determined by HIV RNA testing should be confirmed by standard methods (e.g., Western blot serology) performed 2-4 mo after the initial indeterminate or negative test.

HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 (HIV-1) ANTIGEN (p24), QUALITATIVE (p24 antigen)

Normal range: Negative. This test detects uncomplexed HIV-1 p24 antigen. The core protein p24 is the first detectable protein encoded by the group-specific antigen *(gag)* gene. This protein is a marker for viremia. This test should not be used in place of HIV-1 antibody testing as a screen for HIV-1 infection. HIV-1 p24 may be detectable in the first month of acute HIV-1 infection and generally falls to undetectable levels during the asymptomatic stage of HIV-1 infection. A negative result does not exclude the possibility of infection or exposure to HIV-1. It is recommended that a negative result be followed with repeat testing at least 8 weeks after the original test. This test is used primarily for screening of donated blood and plasma and as an aid for the prognosis of HIV-1 infection.

HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 (HIV-1) VIRAL LOAD

Normal range: HIV-1 RNA, quant. bDNA 3: less than 50 copies/ml or less than 1.7 log copies/ml

This test should be used only in individuals with documented HIV-1 infection for monitoring the progression of infection, response to antiretroviral therapy, and disease prognosis. It is not indicated for diagnosis of HIV infection.

HUMAN PAPILLOMA VIRUS (HPV)

Test description: PCR test can be performed on cervical smears, biopsies, scrapings, liquid cytology specimen, and anogenital tissues.

HUNTINGTON'S DISEASE PCR

Test description: PCR can be performed on whole blood. Huntington's disease is caused by the expansion of the trinucleotide repeat CAG within IT 15 (huntingtin). Pre- and post-test counseling should be performed when ordering this test.

HYDROGEN BREATH TEST

See BREATH HYDROGEN TEST

5-HYDROXYINDOLE-ACETIC ACID, URINE

See URINE 5-HYDROXYINDOLE-ACETIC ACID

HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 (HIV-1) ANTIGEN (p24), QUALITATIVE (p24 antigen)

Normal range: Negative. This test detects uncomplexed HIV-1 p24 antigen. The core protein p24 is the first detectable protein encoded by the group-specific antigen *(gag)* gene. This protein is a marker for viremia. This test should not be used in place of HIV-1 antibody testing as a screen for HIV-1 infection. HIV-1 p24 may be detectable in the first month of acute HIV-1 infection and generally falls to undetectable levels during the asymptomatic stage of HIV-1 infection. A negative result does not exclude the possibility of infection or exposure to HIV-1. It is recommended that a negative result be followed with repeat testing at least 8 weeks after the original test. This test is used primarily for screening of donated blood and plasma and as an aid for the prognosis of HIV-1 infection.

HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 (HIV-1) VIRAL LOAD

Normal range: HIV-1 RNA, quant. bDNA 3: less than 50 copies/ml or less than 1.7 log copies/ml

This test should be used only in individuals with documented HIV-1 infection for monitoring the progression of infection, response to antiretroviral therapy, and disease prognosis. It is not indicated for diagnosis of HIV infection.

HUMAN PAPILLOMA VIRUS (HPV)

Test description: PCR test can be performed on cervical smears, biopsies, scrapings, liquid cytology specimen, and anogenital tissues.

HUNTINGTON'S DISEASE PCR

Test description: PCR can be performed on whole blood. Huntington's disease is caused by the expansion of the trinucleotide repeat CAG within IT 15 (huntingtin). Pre- and post-test counseling should be performed when ordering this test.

HYDROGEN BREATH TEST

See BREATH HYDROGEN TEST

5-HYDROXYINDOLE-ACETIC ACID, URINE

See URINE 5-HYDROXYINDOLE-ACETIC ACID

IMMUNE COMPLEX ASSAY

Normal: Negative
Detected in: Collagen vascular disorders, glomerulonephritis, neoplastic diseases, malaria, primary biliary cirrhosis, chronic acute hepatitis, bacterial endocarditis, vasculitis

IMMUNOGLOBULINS

Normal range:
IgA: 50-350 mg/dl (0.5-3.5 g/L [CF: 0.01; SMI: 0.01 g/L])
IgD: <6 mg/dl (<60 mg/L [CF: 0.01; SMI: 0.01 g/L])
IgE: <25 μg/dl (<0.00025 g/L [CF: 0.01; SMI: 0.01 g/L])
IgG: 800-1500 mg/dl (8-15 g/L [CF: 0.01; SMI: 0.01 g/L])
IgM: 45-150 mg/dl (0.45-1.5 g/L [CF: 0.01; SMI: 0.01 g/L])

Elevated in:
IgA: Lymphoproliferative disorders, Berger's nephropathy, chronic infections, autoimmune disorders, liver disease
IgE: Allergic disorders, parasitic infections, immunologic disorders, IgE myeloma
IgG: Chronic granulomatous infections, infectious diseases, inflammation, myeloma, liver disease
IgM: Primary biliary cirrhosis, infectious diseases (brucellosis, malaria), Waldenström's macroglobulinemia, liver disease

Decreased in:
IgA: Nephrotic syndrome, protein-losing enteropathy, congenital deficiency, lymphocytic leukemia, ataxia-telangiectasia, chronic sinopulmonary disease
IgE: Hypogammaglobulinemia, neoplasma (breast, bronchial, cervical), ataxia-telangiectasia
IgG: Congenital or acquired deficiency, lymphocytic leukemia, phenytoin, methylprednisolone, nephrotic syndrome, protein-losing enteropathy
IgM: Congenital deficiency, lymphocytic leukemia, nephrotic syndrome

INFLUENZA A AND B TESTS

Test description: PCR can be performed on nasopharyngeal swab, wash, or aspirate
Normal: Negative

INSULIN AUTOANTIBODIES

Normal: Negative
Present in: Exogenous insulin from insulin therapy. The presence of islet cell antibodies indicates ongoing beta cell destruction. This test is useful in the early diagnosis of type 1a diabetes mellitus and in the identification of patients at high risk for type 1a diabetes.

INSULIN, FREE

Normal: <17 mcU/ml
Elevated in: Insulin overdose, insulin resistance syndromes, endogenous hyperinsulinemia
Decreased in: Inadequately treated type 1 DM

INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) (serum)

Normal range:
Ages 16-24: 182-780 ng/ml
Ages 25-39: 114-492 ng/ml
Ages 40-54: 90-360 ng/ml
Ages >55: 71-290 ng/ml
Elevated in: Adolescence, acromegaly, pregnancy, precocious puberty, obesity
Decreased in: Malnutrition, delayed puberty, diabetes mellitus, hypopituitarism, cirrhosis, old age

INSULIN-LIKE GROWTH FACTOR-II

Normal range: 288-736 ng/ml
Elevated in: Hypoglycemia associated with non–islet cell tumors, hepatoma, and Wilms' tumor
Decreased in: Growth hormone deficiency

INTERNATIONAL NORMALIZED RATIO (INR)

The INR is a comparative rating of prothrombin time (PT) ratios. The INR represents the observed PT ratio adjusted by the International Reference Thromboplastin. It provides a universal result indicative of what the patient's PT result would have been if measured using the primary World Health Organization International Reference reagent. For proper interpretation of INR values, the patient should be on stable anticoagulant therapy.

RECOMMENDED INR RANGES:

Proximal deep vein thrombosis:	2-3
Pulmonary embolism:	2-3
Transient ischemic attacks:	2-3
Atrial fibrillation:	2-3
Mechanical prosthetic valves:	3-4.5
Recurrent venous thromboembolic disease:	3-4.5

INTRINSIC FACTOR ANTIBODIES

Normal: Negative
Present in: Pernicious anemia (>50% of patients). Cyanocobalamin may give false-positive results.

IRON (serum)

Normal: Male: 65-175 mcg/dl; female: 50-1170 mcg/dl
Elevated in: Hemochromatosis, excessive iron therapy, repeated transfusions, lead poisoning, hemolytic anemia, aplastic anemia, pernicious anemia
Decreased in: Iron deficiency anemia, hypothyroidism, chronic infection

IRON-BINDING CAPACITY, TOTAL (TIBC)

Normal range: 250-460 μg/dl (45-82 μmol/L [CF: 0.1791; SMI: 1 μmol/L])
Elevated in: Iron deficiency anemia, pregnancy, polycythemia, hepatitis, weight loss

TABLE 4-14 Serum Iron and Total Iron-Binding Capacity Patterns

SI↓	TIBC↓	Chronic diseases Uremia
SI↓	TIBC↑	Chronic iron deficiency anemia Pregnancy in third trimester
SI↑	TIBC↓	Hemachromatosis Iron therapy overload (TIBC may be normal) Hemolytic anemia; thalassemia; lead poisoning; megaloblastic anemia; aplastic, pyridoxine deficiency, or other sideroblastic anemias
SI↑	TIBC↑	Oral contraceptives Acute hepatitis (some report TIBC is low normal) Chronic hepatitis (some patients)
SI↑	TIBC NL	B_{12} or folate deficiency
SI↓	TIBC NL	Chronic iron deficiency (some patients) Acute infection, surgery, tissue damage
SI NL	TIBC↑	B_{12}/folate deficiency plus iron deficiency

Reprinted from Ravel R: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.
NL, Normal; *SI,* serum iron; *TIBC,* total iron-binding capacity.

Decreased in: Anemia of chronic disease, hemochromatosis, chronic liver disease, hemolytic anemias, malnutrition (protein depletion)

Table 4-14 describes TIBC and serum iron abnormalities.

IRON SATURATION (% TRANSFERRIN SATURATION)

Normal:
Male: 20%-50%
Female: 15%-50%
Elevated in: Hemochromatosis, excessive iron intake, aplastic anemia, thalassemia, vitamin B_6 deficiency
Decreased in: hypochromic anemias, GI malignancy

TABLE 4-14 Serum Iron and Total Iron-Binding Capacity Patterns

SI↓	TIBC↓	Chronic diseases Uremia
SI↓	TIBC↑	Chronic iron deficiency anemia Pregnancy in third trimester
SI↑	TIBC↓	Hemachromatosis Iron therapy overload (TIBC may be normal) Hemolytic anemia; thalassemia; lead poisoning; megaloblastic anemia; aplastic, pyridoxine deficiency, or other sideroblastic anemias
SI↑	TIBC↑	Oral contraceptives Acute hepatitis (some report TIBC is low normal) Chronic hepatitis (some patients)
SI↑	TIBC NL	B_{12} or folate deficiency
SI↓	TIBC NL	Chronic iron deficiency (some patients) Acute infection, surgery, tissue damage
SI NL	TIBC↑	B_{12}/folate deficiency plus iron deficiency

Reprinted from Ravel R: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.
NL, Normal; *SI,* serum iron; *TIBC,* total iron-binding capacity.

Decreased in: Anemia of chronic disease, hemochromatosis, chronic liver disease, hemolytic anemias, malnutrition (protein depletion)

Table 4-14 describes TIBC and serum iron abnormalities.

IRON SATURATION (% TRANSFERRIN SATURATION)

Normal:
Male: 20%-50%
Female: 15%-50%
Elevated in: Hemochromatosis, excessive iron intake, aplastic anemia, thalassemia, vitamin B_6 deficiency
Decreased in: hypochromic anemias, GI malignancy

LACTATE (blood)

Normal range: 0.5-2.0 mEq/L
Elevated in: Tissue hypoxia (shock, respiratory failure, severe CHF, severe anemia, carbon monoxide or cyanide poisoning), systemic disorders (liver or renal failure, seizures), abnormal intestinal flora (D-lactic acidosis), drugs or toxins (salicylates, ethanol, methanol, ethylene glycol), G6PD deficiency

LACTATE DEHYDROGENASE (LDH)

Normal range: 50-150 U/L (0.82-2.66 μkat/L [CF: 0.01667; SMI: 0.02 μkat/L])
Elevated in:
Infarction of myocardium, lung, kidney
Diseases of cardiopulmonary system, liver, collagen, central nervous system
Hemolytic anemias, megaloblastic anemias, transfusions, seizures, muscle trauma, muscular dystrophy, acute pancreatitis, hypotension, shock, infectious mononucleosis, inflammation, neoplasia, intestinal obstruction, hypothyroidism

LACTATE DEHYDROGENASE ISOENZYMES

Normal range:
LDH_1: 22%-36% (cardiac, red blood cell) (0.22-0.36 [CF: 0.01, SMI: 0.01])
LDH_2: 35%-46% (cardiac, red blood cell) (0.35-0.46)
LDH_3: 13%-26% (pulmonary) (0.15-0.26)
LDH_4: 3%-10% (striated muscle, liver) (0.03-0.1)
LDH_5: 2%-9% (striated muscle, liver) (0.02-0.09)
Normal ratios:
$LDH_1 < LDH_2$
$LDH_5 < LDH_4$
Abnormal values:
$LDH_1 > LDH_2$: Myocardial infarction (can also be seen with hemolytic anemias, pernicious anemia, folate deficiency, renal infarct)
$LDH_5 > LDH_4$: Liver disease (cirrhosis, hepatitis, hepatic congestion)

LACTOSE TOLERANCE TEST (serum)

Normal: Test is performed by giving 2 g/kg body weight lactose orally and drawing glucose level at 0, 30, 45, 60, and 90 min. Normal response is change in glucose from fasting value to >30 mg/dl. Inconclusive response is increase of 20-30 mg/dl, abnormal response is increase <20 mg/dl.
Abnormal in: Lactase deficiency

LAP SCORE

See LEUKOCYTE ALKALINE PHOSPHATASE

LEAD

Normal: Child, <10 mcg/dl; adult, <25 mcg/dl; acceptable for industrial exposure, <50 mcg/dl
Elevated in: Lead exposure, lead poisoning

LDH

See LACTATE DEHYDROGENASE

LDL

See LOW-DENSITY LIPOPROTEIN CHOLESTEROL

LEGIONELLA TITER

Normal: Negative
Positive in: Legionnaire's disease (presumptive: ≥1:256 titer; definitive: fourfold titer increase to ≥1:128)

LEGIONELLA PNEUMOPHILA PCR

Test description: PCR can be performed on lung tissue, water sputum, bronchoalveolar lavage, and other respiratory fluids.

LEUKOCYTE ALKALINE PHOSPHATASE (LAP)

Normal range: 13-100 (33-188 U)
Elevated in: Leukemoid reactions, neutrophilia secondary to infections (except in sickle cell crisis—no significant increase in LAP score), Hodgkin's disease, polycythemia vera, hairy cell leukemia, aplastic anemia, Down's syndrome, myelofibrosis
Decreased in: Acute and chronic granulocytic leukemia, thrombocytopenic purpura, paroxysmal nocturnal hemoglobinuria, hypophosphatemia, collagen disorders

LEUKOCYTE COUNT

See COMPLETE BLOOD COUNT

LIPASE

Normal range: 0-160 U/L (0-2.66 μkat/L [CF: 0.01667; SMI: 0.02 μkat/L])
Elevated in: Acute pancreatitis, perforated peptic ulcer, carcinoma of pancreas (early stage), pancreatic duct obstruction, bowel infarction, intestinal obstruction

LIPOPROTEIN(a)

Normal: Male: 1.35-19.6 mg/dl; female: 1.24-20.1 mg/dl
Elevated in: Coronary artery disease, uncontrolled diabetes, hypothyroidism, chronic renal failure, pregnancy, tobacco use, infections, nephritic syndrome
Decreased in: Niacin, omega-3 fatty acids, estrogens, tamoxifen, statins

LIPOPROTEIN CHOLESTEROL, HIGH-DENSITY

See HIGH-DENSITY LIPOPROTEIN CHOLESTEROL

LIPOPROTEIN CHOLESTEROL, LOW-DENSITY

See LOW-DENSITY LIPOPROTEIN CHOLESTEROL

LIVER KIDNEY MICROSOME TYPE 1 ANTIBODIES (LKM1)

Normal: <20 U
Elevated in: Autoimmune hepatitis type 2

LKM1

See LIVER KIDNEY MICROSOME TYPE 1 ANTIBODIES

LOW-DENSITY LIPOPROTEIN (LDL) CHOLESTEROL

Normal range: 50-130 mg/dl (1.30-1.68 mmol/L [CF: 0.02586; SMI: 0.05 mmol/L])

<70	Optimal in diabetics, prior MI, and patients with cardiac risk factors
100-129	Near or above optimal
130-159	Borderline high
160-189	High
≥190	Very high

LUPUS ANTICOAGULANT

See CIRCULATING ANTICOAGULANT

LUTEINIZING HORMONE

Normal range: 5-25 mIU/ml

Elevated in: Postmenopause, pituitary adenoma, primary gonadal dysfunction, polycystic ovary syndrome

Decreased in: Severe illness, anorexia nervosa, malnutrition, pituitary or hypothalamic impairment, severe stress

LYME DISEASE ANTIBODY TITER

Normal range: Negative

Positive result: Fig. 4-11 illustrates the usual serologic response in Lyme disease.

A serologic test is not necessary or helpful for several days after a tick bite because it is only 40%-50% sensitive in this stage, and a negative test does not rule out the diagnosis.

LYMPHOCYTES

Normal range: 15%-40%

Total lymphocyte count = 800-2600/mm^3

Total T lymphocyte: = 800-2200/mm^3

CD4 lymphocytes = ≥400/mm^3

CD8 lymphocytes = 200-800/mm^3

Normal CD4/CD8 ratio is 2.0.

Elevated in: Chronic infections, infectious mononucleosis and other viral infections, chronic lymphocytic leukemia, Hodgkin's disease, ulcerative colitis, hypoadrenalism, idiopathic thrombocytopenia

Decreased in:

AIDS, bone marrow suppression from chemotherapeutic agents or chemotherapy, aplastic anemia, neoplasms, steroids, adrenocortical hyperfunction, neurologic disorders (multiple sclerosis, myasthenia gravis, Guillain-Barré syndrome)

CD4 lymphocytes are calculated as total white blood cells × % lymphocytes × % lymphocytes stained with CD4. They are decreased in AIDS and other immune dysfunction.

Table 4-15 describes various lymphocyte abnormalities in peripheral blood.

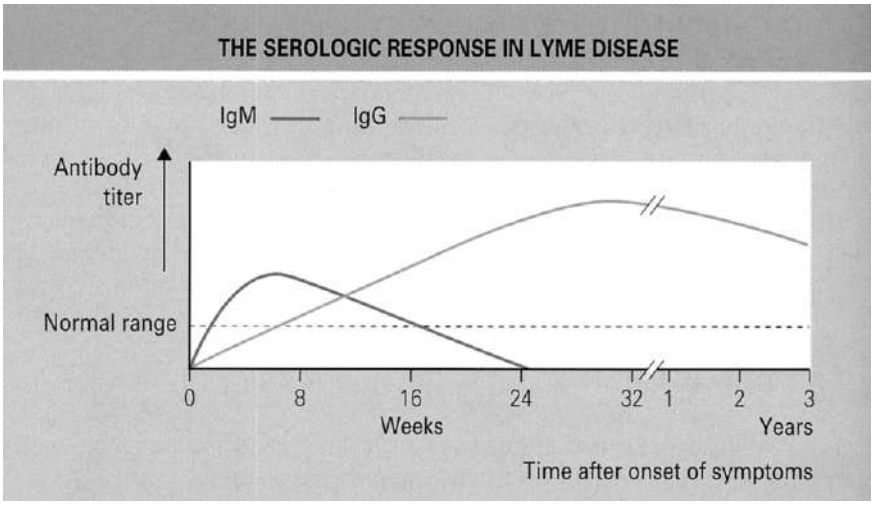

FIGURE 4-11 IgM and IgG responses in Lyme disease.

TABLE 4-15 Differential Diagnosis of Abnormal Lymphocytes in Peripheral Blood

Lymphocyte Type	Usual Disease Association	Cytologic Features	Laboratory Features	Clinical Features
Small lymphocyte	Chronic lymphocytic leukemia	B-cell surface markers with low concentration of surface immunoglobulin, CD5 antigen	Hypogammaglobulinemia in 50%; positive direct Coombs test in 15%; on node biopsy, diffuse, well-differentiated lymphocytic infiltrate	Elderly adults; presentation runs gamut from asymptomatic with lymphocytosis only to bulky disease with adenopathy, splenomegaly, and "packed" bone marrow
Atypical lymphocyte	Infectious mononucleosis, other viral illnesses	Suppressor T-cell markers	Heterophil agglutinin; positive serology for Epstein-Barr virus, cytomegalovirus, toxoplasma, HBsAg	Pharyngitis, fever, adenopathy, rash, splenomegaly, palatal petechiae, jaundice
Plasmacytoid lymphocyte	Waldenström's macroglobulin anemia	Cytoplasmic IgM, periodic acid-Schiff positivity	IgM paraprotein, rouleaux, cryoglobulins	Adenopathy, splenomegaly, absence of bone lesions, hyperviscosity syndrome, cryopathic phenomena
Lymphoblast	ALL	Terminal transferase positivity, common ALL antigen, B- or T-precursor markers	Anemia, granulocytopenia, thrombocytopenia, hyperuricemia, diffuse bone marrow infiltration	Peak incidence in childhood, acute onset, bone pain frequent
Lymphosarcoma cell	Lymphocytic lymphoma	B-cell surface markers with high concentration of monoclonal surface immunoglobulin	Nodular or diffuse, poorly differentiated lymphocytic lymphoma on node biopsy, patchy, peritrabecular bone marrow involvement	Middle-aged to older adults, generalized adenopathy, constitutional symptoms
Sézary cell	Cutaneous lymphomas	T-lymphocyte surface markers	Skin biopsy is diagnostic	Exfoliative erythroderma, cutaneous plaques or tumors
Hairy cell	Hairy cell leukemia	B-lymphocyte markers, cytoplasmic projections, tartrate-resistant acid phosphatase, interleukin-2 receptors, CD11 antigen	Pancytopenia	Middle-aged males, moderate to marked splenomegaly without adenopathy
Prolymphocyte	Prolymphocytic leukemia	B-cell surface markers with high concentration of surface immunoglobulin, CD5 negative	Marked lymphocytosis (frequently $>100 \times 10^9$/L)	Elderly adults, massive splenomegaly, minimum adenopathy, poor response to therapy

Reprinted from Stein JH (ed): *Internal medicine,* ed 5, St Louis, 1998, Mosby.
ALL, Acute lymphoblastic leukemia.

LOW-DENSITY LIPOPROTEIN (LDL) CHOLESTEROL

Normal range: 50-130 mg/dl (1.30-1.68 mmol/L [CF: 0.02586; SMI: 0.05 mmol/L])

<70	Optimal in diabetics, prior MI, and patients with cardiac risk factors
100-129	Near or above optimal
130-159	Borderline high
160-189	High
≥190	Very high

See CIRCULATING ANTICOAGULANT

LUTEINIZING HORMONE

Normal range: 5-25 mIU/ml

Elevated in: Postmenopause, pituitary adenoma, primary gonadal dysfunction, polycystic ovary syndrome

Decreased in: Severe illness, anorexia nervosa, malnutrition, pituitary or hypothalamic impairment, severe stress

LYME DISEASE ANTIBODY TITER

Normal range: Negative

Positive result: Fig. 4-11 illustrates the usual serologic response in Lyme disease.

A serologic test is not necessary or helpful for several days after a tick bite because it is only 40%-50% sensitive in this stage, and a negative test does not rule out the diagnosis.

LYMPHOCYTES

Normal range: 15%-40%

Total lymphocyte count = 800-2600/mm^3

Total T lymphocyte: = 800-2200/mm^3

CD4 lymphocytes = ≥400/mm^3

CD8 lymphocytes = 200-800/mm^3

Normal CD4/CD8 ratio is 2.0.

Elevated in: Chronic infections, infectious mononucleosis and other viral infections, chronic lymphocytic leukemia, Hodgkin's disease, ulcerative colitis, hypoadrenalism, idiopathic thrombocytopenia

Decreased in:

AIDS, bone marrow suppression from chemotherapeutic agents or chemotherapy, aplastic anemia, neoplasms, steroids, adrenocortical hyperfunction, neurologic disorders (multiple sclerosis, myasthenia gravis, Guillain-Barré syndrome)

CD4 lymphocytes are calculated as total white blood cells × % lymphocytes × % lymphocytes stained with CD4. They are decreased in AIDS and other immune dysfunction.

Table 4-15 describes various lymphocyte abnormalities in peripheral blood.

MAGNESIUM (serum)

Normal range: 1.8-3.0 mg/dl (0.80-1.20 mmol/L [CF: 0.4114; SMI: 0.02 mmol/L])

CAUSES OF HYPERMAGNESEMIA

I. Decreased renal excretion
   - A. Renal failure—glomerular filtration rate less than 30 ml/min
   - B. Hyperparathyroidism
   - C. Hypothyroidism
   - D. Addison's disease
   - E. Lithium intoxication
   - F. Familial hypocalciuric hypercalcemia

II. Other causes: usually in association with decrease in glomerular filtration rate
   - A. Endogenous loads
     1. Diabetic ketoacidosis
     2. Severe tissue injury—burns
   - B. Exogenous loads
     1. Gastrointestinal
        - a. Magnesium-containing laxatives and antacids
        - b. High-dose vitamin D analogs
     2. Parenteral: management of toxemia of pregnancy

CAUSES OF HYPOMAGNESEMIA

Alcoholic abuse
Diuretic use
Renal losses
Acute and chronic renal failure
Postobstructive diuresis
Acute tubular necrosis
Chronic glomerulonephritis
Chronic pyelonephritis
Interstitial nephropathy
Renal transplantation
Gastrointestinal losses
Chronic diarrhea
Nasogastric suctioning
Short bowel syndrome
Protein calorie malnutrition
Bowel fistula
Total parenteral nutrition
Acute pancreatitis
Endocrine
Diabetes mellitus
Hyperaldosteronism
Hyperthyroidism
Hyperparathyroidism
Acute intermittent porphyria
Pregnancy
Drugs

ALL, Acute lymphoblastic leukemia.

Aminoglycosides
Amphotericin
β-agonists
Cisplatin
Cyclosporine
Diuretics
Foscarnet
Pentamidine
Theophylline
Congenital disorders
Familial hypomagnesemia
Maternal diabetes
Maternal hypothyroidism
Maternal hyperparathyroidism

MEAN CORPUSCULAR VOLUME (MCV)

Normal range: 76-100 μm^3 (76-100 fL) (76-100 fL [CF: 1; SMI: 1 fL])
See Tables 4-16 and 4-17 for descriptions of MCV abnormalities.

METANEPHRINES, URINE

See URINE METANEPHRINES

METHYLMALONIC ACID, SERUM

Normal: <0.2 mcmol/L
Elevated in: Vitamin B_{12} deficiency, pregnancy, methylmalonic acidemia

MITOCHONDRIAL ANTIBODY (AMA)

Normal: Negative
Present in: Primary biliary cirrhosis (>90% of patients)

MONOCYTE COUNT

Normal range: 2%-8%
Elevated in: Viral diseases, parasites, infections, neoplasms, inflammatory bowel disease, monocytic leukemia, lymphomas, myeloma, sarcoidosis
Decreased in: Aplastic anemia, lymphocytic leukemia, glucocorticoid administration

MYCOPLASMA PNEUMONIAE PCR

Test description: PCR can be performed on sputum, bronchoalveolar lavage, nasopharyngeal and throat swabs, other respiratory fluids, and lung tissue

MYELIN BASIC PROTEIN, CEREBROSPINAL FLUID

Normal: <2.5 ng/ml
Elevated in: Multiple sclerosis, CNS trauma, stroke, encephalitis

MYOGLOBIN, URINE

See URINE MYOGLOBIN

TABLE 4-16 Some Causes of Increased Mean Corpuscular Volume (Macrocytosis)

Causes	% of all Macrocytosis Patients*	% of Macrocytosis in Each Disease†
Common		
Folate or B_{12} deficiency	20-30 (5-50)‡	80-90 (4-100)
Chronic liver disease	15-20 (6-28)	25-30 (8-65)
Chronic alcoholism	10-12 (3-15)	60 (26-90)
Cytotoxic chemotherapy	10-15 (2-20)	30-40 (13-82)
Cardiorespiratory abnormality	8 (7-9.5)	?
Reticulocytosis	6-7 (0-15)	Depends on severity
Myelodysplastic syndromes	Frequent over age 40 yr	>60 in RAEB and RARS
Unexplained	25 (22.5-27)	—
Normal newborn		
Less Common	**<4%**	
Noncytotoxic drugs		
Zidovudine		
Phenytoin		30 (14-50)
Azathioprine		
Hypothyroidism		20-30 (8-55)
Chronic leukemia/myelofibrosis		
Radiotherapy for malignancy		
Chronic renal disease (occasional patients)		
Distance-runner macrocytosis (some persons)		
Down syndrome

See Tables 4-16 and 4-17 for descriptions of MCV abnormalities.

METANEPHRINES, URINE

See URINE METANEPHRINES

METHYLMALONIC ACID, SERUM

Normal: <0.2 mcmol/L
Elevated in: Vitamin B_{12} deficiency, pregnancy, methylmalonic acidemia

MITOCHONDRIAL ANTIBODY (AMA)

Normal: Negative
Present in: Primary biliary cirrhosis (>90% of patients)

MONOCYTE COUNT

Normal range: 2%-8%
Elevated in: Viral diseases, parasites, infections, neoplasms, inflammatory bowel disease, monocytic leukemia, lymphomas, myeloma, sarcoidosis
Decreased in: Aplastic anemia, lymphocytic leukemia, glucocorticoid administration

MYCOPLASMA PNEUMONIAE PCR

Test description: PCR can be performed on sputum, bronchoalveolar lavage, nasopharyngeal and throat swabs, other respiratory fluids, and lung tissue

MYELIN BASIC PROTEIN, CEREBROSPINAL FLUID

Normal: <2.5 ng/ml
Elevated in: Multiple sclerosis, CNS trauma, stroke, encephalitis

MYOGLOBIN, URINE

See URINE MYOGLOBIN

NEISSERIA GONORRHOEA PCR

Test description: Test can be performed on endocervical swab, urine, and intraurethral swab
Normal: Negative

NEUTROPHIL COUNT

Normal range: 50%-70%
Subsets:
Stabs (bands, early mature neutrophils): 2%-6%
Segs (mature neutrophils): 60%-70%
Elevated in: Acute bacterial infections, acute myocardial infarction, stress, neoplasms, myelocytic leukemia
Decreased in: Viral infections, aplastic anemias, immunosuppressive drugs, radiation therapy to bone marrow, agranulocytosis, drugs (antibiotics, antithyroidals, clopidogrel), lymphocytic and monocytic leukemias
Table 4-18 describes various drugs that can cause neutropenia.

NOREPINEPHRINE

Normal range: 0-600 pg/ml
Elevated in: Pheochromocytomas, neuroblastomas, stress, vigorous exercise, certain foods (bananas, chocolate, coffee, tea, vanilla)

TABLE 4-16 Some Causes of Increased Mean Corpuscular Volume (Macrocytosis)

Causes	% of all Macrocytosis Patients*	% of Macrocytosis in Each Disease†
Common		
Folate or B_{12} deficiency	20-30 (5-50)‡	80-90 (4-100)
Chronic liver disease	15-20 (6-28)	25-30 (8-65)

5′-NUCLEOTIDASE

Normal range: 2-16 IU/L (3-27 $\times$ 10^8 kat/L [CF: 1.67 $\times$ 10^8; SMI: 1 $\times$ 10^8 kat/L])
Elevated in: Biliary obstruction, metastatic neoplasms to liver, primary biliary cirrhosis, renal failure, pancreatic carcinoma, chronic active hepatitis

TABLE 4-18 Drugs That Cause Neutropenia

Antiarrhythmics
Tocainide, procainamide, propranolol, quinidine
Antibiotics
Chloramphenicol, penicillins, sulfonamides, p-aminosalicylic acid (PAS), rifampin, vancomycin, isoniazid, nitrofurantoin
Antimalarials
Dapsone, quinine, pyrimethamine
Anticonvulsants
Phenytoin, mephenytoin, trimethadione, ethosuximide, carbamazepine
Hypoglycemic agents
Tolbutamide, chlorpropamide
Antihistamines
Cimetidine, brompheniramine, tripelennamine
Antihypertensives
Methyldopa, captopril
Anti-inflammatory agents
Aminopyrine, phenylbutazone, gold salts, ibuprofen, indomethacin
Antithyroid agents
Propylthiouracil, methimazole, thiouracil
Diuretics
Acetazolamide, hydrochlorothiazide, chlorthalidone
Phenothiazines
Chlorpromazine, promazine, prochlorperazine
Immunosuppressive agents
Antimetabolites
Cytotoxic agents
Alkylating agents, antimetabolites, anthracyclines, Vinca alkaloids, cisplatin, hydroxyurea, dactinomycin
Other agents
Recombinant interferons, allopurinol, ethanol, levamisole, penicillamine, zidovudine, streptokinase, carbamazepine, clopidogrel, ticlopidine

Modified from Goldman L, Ausiello D (eds): *Cecil textbook of medicine,* ed 22, Philadelphia, 2004, WB Saunders.

5′-NUCLEOTIDASE

Normal range: 2-16 IU/L (3-27 × 10^8 kat/L [CF: 1.67 × 10^8; SMI: 1 × 10^8 kat/L])
Elevated in: Biliary obstruction, metastatic neoplasms to liver, primary biliary cirrhosis, renal failure, pancreatic carcinoma, chronic active hepatitis

OSMOLALITY (serum)

Normal range: 280-300 mOsm/kg (280-300 mmol/kg [CF: 1; SMI: 1 mmol/kg])

It can also be estimated by the following formula:

$$2([Na] + [K]) + glucose/18 + BUN/2.8$$

Elevated in: Dehydration, hypernatremia, diabetes insipidus, uremia, hyperglycemia, mannitol therapy, ingestion of toxins (ethylene glycol, methanol, ethanol), hypercalcemia, diuretics
Decreased in: Syndrome of inappropriate diuretic hormone secretion, hyponatremia, overhydration, Addison's disease, hypothyroidism

OSMOLALITY, URINE

See URINE OSMOLALITY

TABLE 4-18 Drugs That Cause Neutropenia

Antiarrhythmics
  Tocainide, procainamide, propranolol, quinidine
Antibiotics
  Chloramphenicol, penicillins, sulfonamides, p-aminosalicylic acid (PAS), rifampin, vancomycin, isoniazid, nitrofurantoin
Antimalarials
  Dapsone, quinine, pyrimethamine
Anticonvulsants

Modified from Goldman L, Ausiello D (eds): *Cecil textbook of medicine,* ed 22, Philadelphia, 2004, WB Saunders.

OSMOTIC FRAGILITY TEST

Normal: Hemolysis begins at 0.50, w/v [5.0 g/L] and is complete at 0.30, w/v [3.0 g/L] NaCl.
Elevated in: Hereditary spherocytosis, hereditary stomatocytosis, spherocytosis associated with acquired immune hemolytic anemia
Decreased in: Iron deficiency anemia, thalassemias, liver disease, leptocytosis associated with asplenia

OSMOTIC FRAGILITY TEST

Normal: Hemolysis begins at 0.50, w/v [5.0 g/L] and is complete at 0.30, w/v [3.0 g/L] NaCl.
Elevated in: Hereditary spherocytosis, hereditary stomatocytosis, spherocytosis associated with acquired immune hemolytic anemia
Decreased in: Iron deficiency anemia, thalassemias, liver disease, leptocytosis associated with asplenia

PARACENTESIS FLUID

Testing and evaluation of results:

1. Process the fluid as follows:
   a. Tube 1: LDH, glucose, albumin
   b. Tube 2: protein, specific gravity
   c. Tube 3: cell count and differential
   d. Tube 4: save until further notice
2. Draw serum LDH, protein, albumin.
3. Gram stain, AFB stain, bacterial and fungal cultures, amylase, and triglycerides should be ordered only when clearly indicated; bedside inoculation of blood-culture bottles with ascitic fluid improves sensitivity in detecting bacterial growth.
4. If malignant ascites is suspected, consider a carcinoembryonic antigen level on the paracentesis fluid and cytologic evaluation.
5. In suspected spontaneous bacterial peritonitis (SBP) the incidence of positive cultures can be increased by injecting 10 to 20 ml of ascitic fluid into blood culture bottles.
6. Peritoneal effusion can be subdivided as exudative or transudative based on its characteristics (see Section II).
7. The serum-ascites albumin gradient (serum albumin level–ascitic fluid albumin level) correlates directly with portal pressure and can also be used to classify ascite. Patients with gradients $\geq$1.1 g/dl have portal hypertension, and those with gradients $\leq$1.1 g/dl do not; the accuracy of this method is $>$95%.
8. For the differential diagnosis of ascites, refer to Section II.
9. An ascitic fluid polymorphonuclear leukocyte count $>$500/μl is suggestive of SBP.
10. A blood-ascitic fluid albumin gradient.

PARATHYROID HORMONE (PTH)

Normal:
Serum, intact molecule 10-65 pg/ml
Plasma 1.0-5.0 pmol/L
Elevated in: hyperparathyroidism (primary or secondary), pseudohypoparathyroidism, anticonvulsants, corticosteroids, lithium, INH, rifampin, phosphates, ZE syndrome, hereditary vitamin D deficiency
Decreased in: hypoparathyroidism, sarcoidosis, cimetidine, beta-blockers, hyperthyroidism, hypomagnesemia

PARIETAL CELL ANTIBODIES

Normal: Negative
Present in: Pernicious anemia ($>$90%), atrophic gastritis (up to 50%), thyroiditis (30%), Addison's disease, myasthenia gravis, Sjögren's syndrome, type 1 DM

PARTIAL THROMBOPLASTIN TIME (PTT), ACTIVATED PARTIAL THROMBOPLASTIN TIME (APTT)

Normal range: 25-41 sec
Elevated in: Heparin therapy, coagulation factor deficiency (I, II, V, VIII, IX, X, XI, XII), liver disease, vitamin K deficiency, disseminated intravascular coagulation, circulating anticoagulant, warfarin therapy, specific factor inhibition (PCN reaction, rheumatoid arthritis), thrombolytic therapy, nephrotic syndrome
NOTE: Useful to evaluate the intrinsic coagulation system.

PEPSINOGEN I

Normal: 124-142 ng/ml
Elevated in: ZE syndrome, duodenal ulcer, acute gastritis
Decreased in: Atrophic gastritis, gastric carcinoma, myxedema, pernicious anemia, Addison's disease

pH, BLOOD

Normal values:
Arterial: 7.35-7.45
Venous: 7.32-7.42
For abnormal values, refer to ARTERIAL BLOOD GASES.

pH, URINE

See URINE pH

PHENOBARBITAL

Normal therapeutic range: 15-30 mcg/ml for epilepsy control

PHENYTOIN (Dilantin)

Normal therapeutic range: 10-20 mcg/ml

PHOSPHATASE, ACID

See ACID PHOSPHATASE

PHOSPHATASE, ALKALINE

See ALKALINE PHOSPHATASE

PHOSPHATE (serum)

Normal range: 2.5-5 mg/dl (0.8-1.6 mmol/L [CF: 0.3229; SMI: 0.05 mmol/L])
DECREASED
Parenteral hyperalimentation
Diabetic acidosis
Alcohol withdrawal
Severe metabolic or respiratory alkalosis
Antacids that bind phosphorus
Malnutrition with refeeding using low-phosphorus nutrients
Renal tubule failure to reabsorb phosphate (Fanconi's syndrome; congenital disorder; vitamin D deficiency)
Glucose administration
Nasogastric suction
Malabsorption
Gram-negative sepsis
Primary hyperthyroidism
Chlorothiazide diuretics
Therapy of acute severe asthma
Acute respiratory failure with mechanical ventilation
INCREASED
Renal failure
Severe muscle injury
Phosphate-containing antacids
Hypoparathyroidism
Tumor lysis syndrome

PLASMINOGEN

Normal: Immunoassay (antigen): $<$20 mg/dl
Elevated in: infection, trauma, neoplasm, myocardial infarction (acute phase reactant), pregnancy, bilirubinemia
Decreased in: DIC, severe liver disease, thrombolytic therapy with streptokinase or urokinase, alteplase

PLATELET AGGREGATION

Normal: Full aggregation (generally $>$60%) in response to epinephrine, thrombin, ristocetin, ADP, collagen
Elevated in: Heparin, hemolysis, lipemia, nicotine, hereditary and acquired disorders of platelet adhesion, activation, and aggregation
Decreased in: Aspirin, some penicillins, chloroquine, chlorpromazine, clofibrate, captopril, Glanzmann's thrombasthenia, Bernard-Soulier syndrome, Wiskott-Aldrich syndrome, cyclooxygenase deficiency. In von Willebrand's disease there is normal aggregation with ADP, collagen, and epinephrine but abnormal agglutination with ristocetin.

PLATELET ANTIBODIES

Normal: Absent
Present in: ITP (>90% of patients with chronic ITP). Patients with nonimmune thrombocytopenias may have false-positive results.

PLATELET COUNT

Normal range: 130-400 $\times$ 10^3/mm^3 (130-400 $\times$ 10^9/L [CF: 1; SMI: 5 $\times$ 10^9/L])
Elevated in:
REACTIVE THROMBOCYTOSIS
Infections or inflammatory states—vasculitis, allergic reactions, etc.
Surgery and tissue damage—myocardial infarction, pancreatitis, etc.
Postsplenectomy state
Malignancy—solid tumors, lymphoma
Iron deficiency anemia, hemolytic anemia, acute blood loss
Uncertain etiology
Rebound effect after chemotherapy or immune thrombocytopenia
Renal disorders—renal failure, nephrotic syndrome
MYELOPROLIFERATIVE DISORDERS
Chronic myeloid leukemia
Primary thrombocythemia
Polycythemia vera
Idiopathic myelofibrosis
Decreased:
A. Increased destruction
   1. Immunologic
      a. Drugs: quinine, quinidine, digitalis, procainamide, thiazide diuretics, sulfonamides, phenytoin, aspirin, penicillin, heparin, gold, meprobamate, sulfa drugs, phenylbutazone, NSAIDs, methyldopa, cimetidine, furosemide, INH, cephalosporins, chlorpropamide, organic arsenicals, chloroquine
      b. Idiopathic thrombocytopenic purpura
      c. Transfusion reaction: transfusion of platelets with platelet antigen HPA-1a (PL^{A1}) in recipients without PL^{A1}
      d. Fetal/maternal incompatibility
      e. Vasculitis (e.g., systemic lupus erythematosus)
      f. Autoimmune hemolytic anemia
      g. Lymphoreticular disorders (e.g., chronic lymphocytic leukemia)
   2. Nonimmunologic
      a. Prosthetic heart valves
      b. Thrombotic thrombocytopenic purpura
      c. Sepsis
      d. Disseminated intravascular coagulation
      e. Hemolytic-uremic syndrome
      f. Giant cavernous hemangioma
B. Decreased production
   1. Abnormal marrow
      a. Marrow infiltration (e.g., leukemia, lymphoma, fibrosis)
      b. Marrow suppression (e.g., chemotherapy, alcohol, radiation)
   2. Hereditary disorders
      a. Wiskott-Aldrich syndrome: X-linked disorder characterized by thrombocytopenia, eczema, and repeated infections
      b. May-Hegglin anomaly: increased megakaryocytes but ineffective thrombopoiesis
   3. Vitamin deficiencies (e.g., vitamin B_{12}, folic acid)
C. Splenic sequestration, hypersplenism
D. Dilutional, secondary to massive transfusion

PLATELET FUNCTION ANALYSIS 100 ASSAY (PFA)

Normal: This test is a two-component assay where blood is aspirated through two capillary tubes, one of which is coated with collagen and ADP (COL/ADP) and the other with collagen and epinephrine (COL/EPI). The test measures the ability of platelets to occlude an aperture in a biologically active membrane treated with COL/ADP and COL/EPI. During the test, the platelets adhere to the surface of the tube and cause blood flow to cease. The closing time refers to the cessation of blood flow and is reported in conjunction with the hematocrit and platelet count. Hematocrit count must be >25% and platelet count >50 K/microliter for the test to be performed
COL/ADP: 70-120 sec
COL/EPI: 75-120 sec
Elevated in: acquired platelet dysfunction, von Willebrand's disease, anemia, thrombocytopenia, use of aspirin and NSAIDs

POTASSIUM (serum)

Normal range: 3.5-5 mEq/L (3.5-5 mmol/L [CF: 1; SMI: 0.1 mmol/L])
CAUSES OF HYPERKALEMIA
I. Pseudohyperkalemia
   A. Hemolysis of sample
   B. Thrombocytosis
   C. Leukocytosis
   D. Laboratory error
II. Increased potassium intake and absorption
   A. Potassium supplements (oral and parenteral)
   B. Dietary—salt substitutes
   C. Stored blood
   D. Potassium-containing medications
III. Impaired renal excretion
   A. Acute renal failure
   B. Chronic renal failure
   C. Tubular defect in potassium secretion
      1. Renal allograft
      2. Analgesic nephropathy
      3. Sickle cell disease
      4. Obstructive uropathy
      5. Interstitial nephritis
      6. Chronic pyelonephritis
      7. Potassium-sparing diuretics
      8. Miscellaneous (lead, systemic lupus erythematosus, pseudohypoaldosteronism)
   D. Hypoaldosteronism
      1. Primary (Addison's disease)
      2. Secondary
         a. Hyporeninemic hypoaldosteronism (type IV RTA)
         b. Congenital adrenal hyperplasia
         c. Drug-induced
            (1) NSAIDs
            (2) ACE inhibitors
            (3) Heparin
            (4) Cyclosporine
IV. Transcellular shifts
   A. Acidosis
   B. Hypertonicity
   C. Insulin deficiency
   D. Drugs
      1. β-blockers
      2. Digitalis toxicity
      3. Succinylcholine
   E. Exercise
   F. Hyperkalemic periodic paralysis
V. Cellular injury
   A. Rhabdomyolysis
   B. Severe intravascular hemolysis
   C. Acute tumor lysis syndrome
   D. Burns and crush injuries
CAUSES OF HYPOKALEMIA
I. Decreased intake
   A. Decreased dietary potassium
   B. Impaired absorption of potassium
   C. Clay ingestion
   D. Kayexalate
II. Increased loss
   A. Renal
      1. Hyperaldosteronism
         a. Primary
            (1) Conn's syndrome
            (2) Adrenal hyperplasia
         b. Secondary
            (1) Congestive heart failure
            (2) Cirrhosis

(3) Nephrotic syndrome
(4) Dehydration
c. Bartter's syndrome
2. Glycyrrhizic acid (licorice, chewing tobacco)
3. Excessive adrenal corticosteroids
a. Cushing's syndrome
b. Steroid therapy
c. Adrenogenital syndrome
4. Renal tubular defects
a. Renal tubular acidosis
b. Obstructive uropathy
c. Salt-wasting nephropathy
5. Drugs
a. Diuretics
b. Aminoglycosides
c. Mannitol
d. Amphotericin
e. Cisplatin
f. Carbenicillin

B. Gastrointestinal
1. Vomiting
2. Nasogastric suction
3. Diarrhea
4. Malabsorption
5. Ileostomy
6. Villous adenoma
7. Laxative abuse

C. Increased losses from the skin
1. Excessive sweating
2. Burns

III. Transcellular shifts
A. Alkalosis
1. Vomiting
2. Diuretics
3. Hyperventilation
4. Bicarbonate therapy

B. Insulin
1. Exogenous
2. Endogenous response to glucose

C. β_2-Agonists (albuterol, terbutaline, epinephrine)
D. Hypokalemia periodic paralysis
1. Familial
2. Thyrotoxic

IV. Miscellaneous
A. Anabolic state
B. Intravenous hyperalimentation
C. Treatment of megaloblastic anemia
D. Acute mountain sickness

POTASSIUM, URINE

See URINE POTASSIUM

PROCAINAMIDE

Normal therapeutic range: 4-10 mcg/ml

PROGESTERONE (serum)

Normal:
Female: Follicular phase: 15-70 ng/dl
Luteal phase: 200-2500 ng/dl
Male: 15-70 ng/dl
Elevated in: Congenital adrenal hyperplasia, clomiphene, corticosterone, 11-deoxycortisol, dihydroprogesterone, molar pregnancy, lipoid ovarian tumor
Decreased in: Primary or secondary hypogonadism, oral contraceptives, ampicillin, threatened abortion

PROLACTIN

Normal range: <20 ng/ml (<20 μg/L [CF: 1; SMI: 1 μg/L])
Elevated in: Prolactinomas (level >200 highly suggestive), drugs (phenothiazines, cimetidine, tricyclic antidepressants, metoclopramide, estrogens, antihypertensives [methyldopa], verapamil, haloperidol), postpartum, stress, hypoglycemia, hypothyroidism

PROSTATE-SPECIFIC ANTIGEN (PSA)

Normal range: 0-4 ng/ml
Table 4-19 describes age-specific reference ranges for PSA.
Elevated in: Benign prostatic hypertrophy, carcinoma of prostate, prostatitis, postrectal examination, prostate trauma.
Factors affecting serum PSA are described in Table 4-20.
NOTE: Measurement of free PSA is useful to assess the probability of prostate cancer in patients with normal digital rectal examination and total PSA between 4 and 10 ng/ml. In these patients, the global risk of prostate cancer is 25%; however, if the free PSA is >25%, the risk of prostate cancer decreases to 8%, whereas if the free PSA is <10%, the risk of cancer increases to 56%. Free PSA is also useful to evaluate the aggressiveness of prostate cancer. A low free PSA percentage generally indicates a high-grade cancer, whereas a high free PSA percentage is generally associated with a slower growing tumor.
Decreased in: 5 alpha-reductase inhibitors (finasteride, dutasteride), saw palmetto use, antiandrogens

PROSTATIC ACID PHOSPHATASE

Normal: 0-0.8 U/L
Elevated in: Prostate cancer (especially in metastatic prostate cancer), BPH, prostatitis, post–prostate surgery or manipulation, hemolysis, androgens, clofibrate
Decreased in: Ketoconazole

PROTEIN (SERUM)

Normal range: 6-8 g/dl (60-80 g/L [CF: 10; SMI: 1 g/L])
Elevated in: Dehydration, multiple myeloma, Waldenström's macroglobulinemia, sarcoidosis, collagen vascular diseases

TABLE 4-19 Age-Specific Reference Ranges for PSA

	Serum PSA (ng/ml)		
Age (yr)	Whites	Japanese	African Americans
40-49	0-2.5	0-2.0	0-2.0
50-59	0-3.5	0-3.0	0-4.0
60-69	0-4.5	0-4.0	0-4.5
70-79	0-6.5	0-5.0	0-5.5

Reprinted from Nseyo UO (ed): *Urology for primary care physicians,* Philadelphia, 1999, WB Saunders.
PSA, Prostate-specific antigen.

TABLE 4-20 Factors Affecting Serum PSA

Factors Affecting Serum PSA	Duration of Effect
Prostate cell number	NA
Prostate size	NA
Recent ejaculation	6-48 hours
Prostate manipulation	
Vigorous massage	1 week
Cystoscopy	1 week
Prostate biopsy	4-6 weeks
Prostatitis	
Acute	3-6 months
Chronic	Unknown
Prostate cancer	NA
Drugs: finasteride (Proscar)*	3-6 months

Reprinted from Nseyo UO (ed): *Urology for primary care physicians,* Philadelphia, 1999, WB Saunders.
NA, Not applicable; *PSA,* prostate-specific antigen.
*Lowers PSA for as long as patient is on the medication.

Decreased in: Malnutrition, low-protein diet, overhydration, malabsorption, pregnancy, severe burns, neoplasms, chronic diseases, cirrhosis, nephrosis

PROTEIN C ASSAY

Normal: 70%-140%
Elevated in: Oral contraceptives, stanozol
Decreased in: Congenital protein C deficiency, warfarin therapy, Vitamin K deficiency, renal insufficiency, consumptive coagulopathies

PROTEIN ELECTROPHORESIS (serum)

Normal range:
Albumin: 60%-75% (0.6-0.75 [CF: 0.01; SMI: 0.01])
α-1: 1.7%-5% (0.02-0.05)
α-2: 6.7%-12.5% (0.07-0.13)
β: 8.3%-16.3% (0.08-0.16)
γ: 10.7%-20% (0.11-0.2)
Albumin: 3.6-5.2 g/dl (36-52 g/L [CF: 0.01; SMI: 1 g/L])
α-1: 0.1-0.4 g/dl (1-4 g/L)
α-2: 0.4-1 g/dl (4-10 g/L)
β: 0.5-1.2 g/dl (5-12 g/L)
γ: 0.6-1.6 g/dl (6-16 g/L)
Elevated in:
Albumin: dehydration
α-1: neoplastic diseases, inflammation
α-2: neoplasms, inflammation, infection, nephrotic syndrome
β: hypothyroidism, biliary cirrhosis, diabetes mellitus
γ: See IMMUNOGLOBULINS
Decreased in:
Albumin: malnutrition, chronic liver disease, malabsorption, nephrotic syndrome, burns, systemic lupus erythematosus
α-1: emphysema (α-1 antitrypsin deficiency), nephrosis
α-2: hemolytic anemias (decreased haptoglobin), severe hepatocellular damage
β: hypocholesterolemia, nephrosis
γ: See IMMUNOGLOBULINS
Fig. 4-12 describes serum protein electrophoretic patterns.

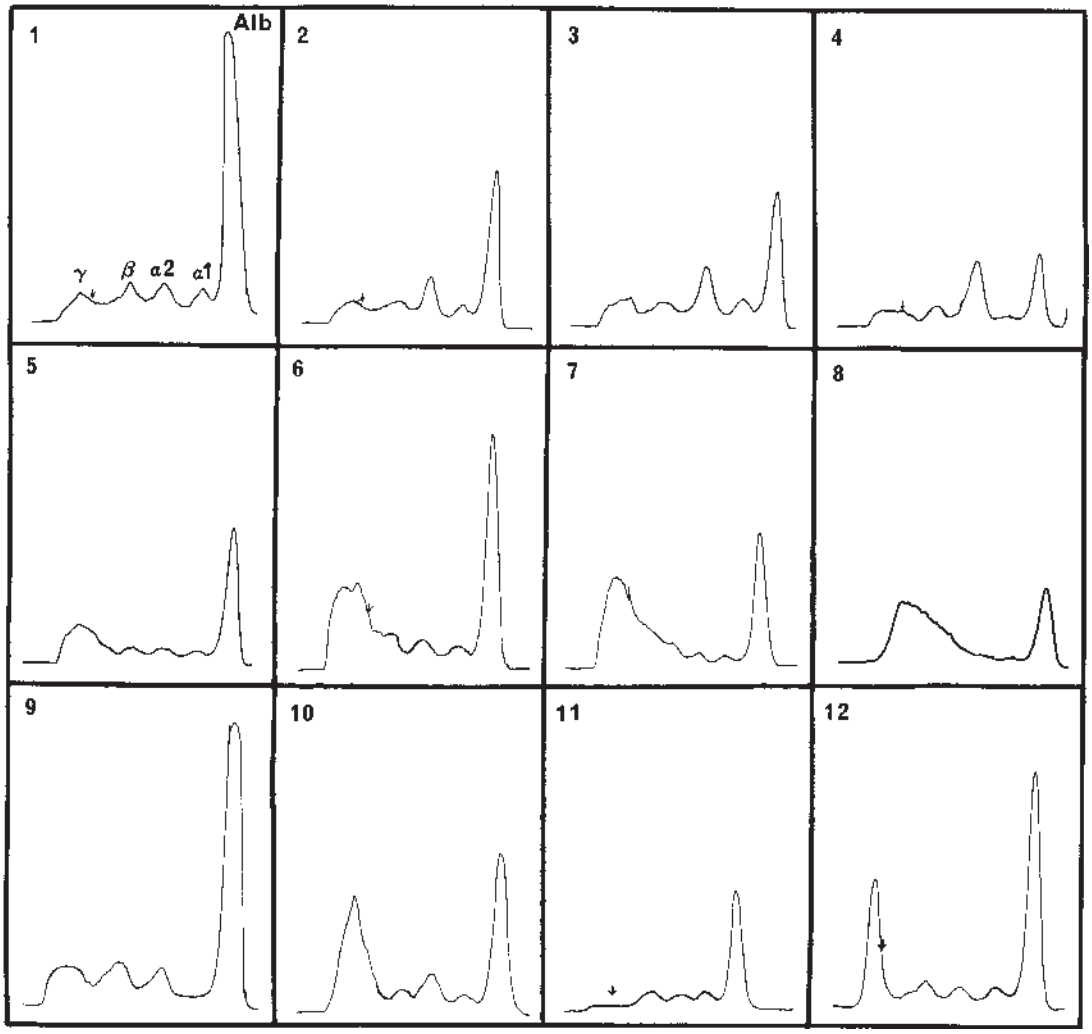

FIGURE 4-12 Typical serum protein electrophoretic patterns. *1,* Normal (*arrow* near γ region indicates serum application point). *2,* Acute reaction pattern. *3,* Acute reaction or nephrotic syndrome. *4,* Nephrotic syndrome. *5,* Chronic inflammation, cirrhosis, granulomatous diseases, rheumatoid-collagen group. *6,* Same as 5, but γ elevation is more pronounced. There is also partial (but not complete) β-γ fusion. *7,* Suggestive of cirrhosis but could be found in the granulomatous diseases or the rheumatoid-collagen group. *8,* Characteristic pattern of cirrhosis. *9,* α-1 Antitrypsin deficiency with mild γ elevation suggesting concurrent chronic disease. *10,* Same as 5, but the γ elevation is marked. The configuration of the γ peak superficially mimics that of myeloma, but is more broad-based. There are superimposed acute reaction changes. *11,* Hypogammaglobulinemia or light-chain myeloma. *12,* Myeloma, Waldenström's macroglobulinemia, idiopathic or secondary monoclonal gammopathy. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

PROTEIN S ASSAY

Normal: 65%-140%
Elevated in: Presence of lupus anticoagulant
Decreased in: Hereditary deficiency, acute thrombotic events, DIC, surgery, oral contraceptives, pregnancy, hormone replacement therapy, L-asparaginase treatment

PROTHROMBIN TIME (PT)

Normal range: 10-12 sec
Elevated in: Liver disease, oral anticoagulants (warfarin), heparin, factor deficiency (I, II, V, VII, X), disseminated intravascular coagulation, vitamin K deficiency, afibrinogenemia, dysfibrinogenemia, drugs (salicylate, chloral hydrate, diphenylhydantoin, estrogens, antacids, phenylbutazone, quinidine, antibiotics, allopurinol, anabolic steroids)
Decreased in: Vitamin K supplementation, thrombophlebitis, drugs (glutethimide, estrogens, griseofulvin, diphenhydramine)

PROTOPORPHYRIN (free erythrocyte)

Normal range: 16-36 μg/dl of red blood cells (0.28-0.64 μmol/L [CF: 0.0177; SMI: 0.02 μmol/L])
Elevated in: Iron deficiency, lead poisoning, sideroblastic anemias, anemia of chronic disease, hemolytic anemias, erythropoietic protoporphyria

PSA

See PROSTATE-SPECIFIC ANTIGEN

PT

See PROTHROMBIN TIME

PTH

See PARATHYROID HORMONE

PTT

See PARTIAL THROMBOPLASTIN TIME

PROTEIN S ASSAY
Normal: 65%-140%
Elevated in: Presence of lupus anticoagulant
Decreased in: Hereditary deficiency, acute thrombotic events, DIC, surgery, oral contraceptives, pregnancy, hormone replacement therapy, L-asparaginase treatment

PROTHROMBIN TIME (PT)
Normal range: 10-12 sec
Elevated in: Liver disease, oral anticoagulants (warfarin), heparin, factor deficiency (I, II, V, VII, X), disseminated intravascular coagulation, vitamin K deficiency, afibrinogenemia, dysfibrinogenemia, drugs (salicylate, chloral hydrate, diphenylhydantoin, estrogens, antacids, phenylbutazone, quinidine, antibiotics, allopurinol, anabolic steroids)
Decreased in: Vitamin K supplementation, thrombophlebitis, drugs (glutethimide, estrogens, griseofulvin, diphenhydramine)

PROTOPORPHYRIN (free erythrocyte)
Normal range: 16-36 μg/dl of red blood cells (0.28-0.64 μmol/L [CF: 0.0177; SMI: 0.02 μmol/L])
Elevated in: Iron deficiency, lead poisoning, sideroblastic anemias, anemia of chronic disease, hemolytic anemias, erythropoietic protoporphyria

PSA
See PROSTATE-SPECIFIC ANTIGEN

PT
See PROTHROMBIN TIME

PTH
See PARATHYROID HORMONE

PTT
See PARTIAL THROMBOPLASTIN TIME

RDW
See RED BLOOD CELL DISTRIBUTION WIDTH

RED BLOOD CELL (RBC) COUNT
Normal range:
Male: 4.3-5.9 $\times$ 10^6/mm^3 (4.3-5.9 $\times$ 10^{12}/L [CF: 1; SMI: 0.1 $\times$ 10^{12}/L])
Female: 3.5-5 $\times$ 10^6/mm^3 (3.5-5 $\times$ 10^{12}/L [CF: 1; SMI: 0.1 $\times$ 10^{12}/L])
Elevated in: Polycythemia vera, smokers, high altitude, cardiovascular disease, renal cell carcinoma and other erythropoietin-producing neoplasms, stress, hemoconcentration/dehydration
Decreased in: Anemias, hemolysis, chronic renal failure, hemorrhage, failure of marrow production

RED BLOOD CELL DISTRIBUTION WIDTH (RDW)
Measures variability of red cell size (anisocytosis)
Normal range: 11.5-14.5
Normal RDW and elevated mean corpuscular volume (MCV): Aplastic anemia, preleukemia
Normal MCV: Normal, anemia of chronic disease, acute blood loss or hemolysis, chronic lymphocytic leukemia (CLL), chronic myelocytic leukemia, nonanemic enzymopathy or hemoglobinopathy
Decreased MCV: Anemia of chronic disease, heterozygous thalassemia
Elevated RDW and elevated MCV: Vitamin B_{12} deficiency, folate deficiency, immune hemolytic anemia, cold agglutinins, CLL with high count, liver disease
Normal MCV: Early iron deficiency, early vitamin B_{12} deficiency, early folate deficiency, anemic globinopathy
Decreased MCV: Iron deficiency, red blood cell fragmentation, HbH disease, thalassemia intermedia

RED BLOOD CELL FOLATE
See FOLATE

RED BLOOD CELL MASS (volume)
Normal range:
Male: 20-36 ml/kg body weight (1.15-1.21 L/m^2 body surface area)
Female: 19-31 ml/kg body weight (0.95-1.00 L/m^2 body surface area)
Elevated in: Polycythemia vera, hypoxia (smokers, high altitude, cardiovascular disease), hemoglobinopathies with high oxygen affinity, erythropoietin-producing tumors (renal cell carcinoma)
Decreased in: Hemorrhage, chronic disease, failure of marrow production, anemias, hemolysis

RED BLOOD CELL MORPHOLOGY
See Fig. 4-13.

RENIN (serum)
Elevated in: Drugs (thiazides, estrogen, minoxidil), chronic renal failure, Bartter's syndrome, pregnancy (normal), pheochromocytoma, renal hypertension, reduced plasma volume, secondary aldosteronism

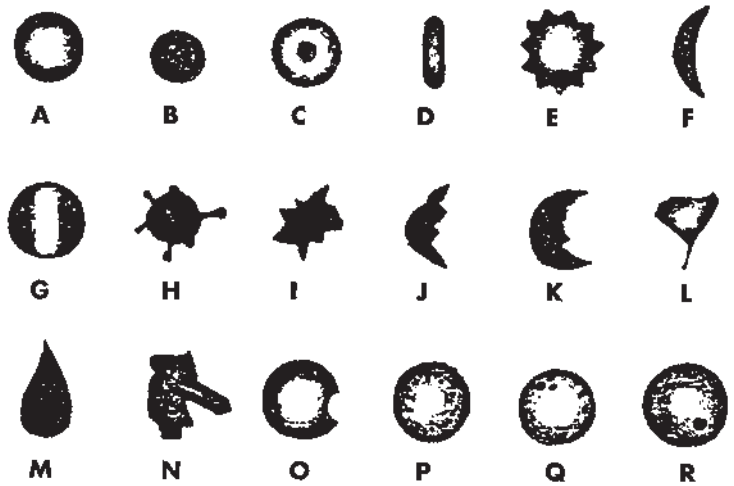

FIGURE 4-13 Abnormal red blood cells (RBCs). A, Normal RBC. **B,** Spherocyte. **C,** Target cell. **D,** Elliptocyte. **E,** Echinocyte. **F,** Sickle cell. **G,** Stomatocyte. **H,** Acanthocyte. **I** to **L,** Schistocytes. **M,** Teardrop RBC. **N,** Distorted RBC with Hb C crystal protruding. **O,** Degmacyte. **P,** Basophilic stippling. **Q,** Pappenheimer bodies. **R,** Howell-Jolly body. (Reprinted from Ravel R [ed]: *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.)

Decreased in: Adrenocortical hypertension, increased plasma volume, primary aldosteronism, drugs (propranolol, reserpine, clonidine)

Table 4-21 describes typical renin-aldosterone patterns in various conditions.

RESPIRATORY SYNCYTIAL VIRUS (RSV) SCREEN

Test description: PCR test can be performed on nasopharyngeal swab, wash, or aspirate

RETICULOCYTE COUNT

Normal range: 0.5%-1.5%
Elevated in: Hemolytic anemia (sickle cell crisis, thalassemia major, autoimmune hemolysis), hemorrhage, postanemia therapy (folic acid, ferrous sulfate, vitamin B_{12}), chronic renal failure
Decreased in: Aplastic anemia, marrow suppression (sepsis, chemotherapeutic agents, radiation), hepatic cirrhosis, blood transfusion, anemias of disordered maturation (iron deficiency anemia, megaloblastic anemia, sideroblastic anemia, anemia of chronic disease)

RHEUMATOID FACTOR

Normal: Negative. Present in titer >1:20
RHEUMATIC DISEASES
Rheumatoid arthritis
Sjögren's syndrome
Systemic lupus erythematosus
Polymyositis/dermatomyositis
Mixed connective tissue disease
Scleroderma
INFECTIOUS DISEASES
Subacute bacterial endocarditis
Tuberculosis
Infectious mononucleosis
Hepatitis
Syphilis
Leprosy
Influenza
MALIGNANCIES
Lymphoma
Multiple myeloma
Waldenström's macroglobulinemia
Postradiation or postchemotherapy
MISCELLANEOUS
Normal adults, especially the elderly
Sarcoidosis
Chronic pulmonary disease (interstitial fibrosis)
Chronic liver disease (chronic active hepatitis, cirrhosis)
Mixed essential cryoglobulinemia
Hypergammaglobulinemic purpura

TABLE 4-21 Typical Renin-Aldosterone Patterns in Various Conditions

	Plasma Renin	Aldosterone
Primary aldosteronism	Low	High
"Low-renin" essential hypertension	Low	Normal
Cushing's syndrome	Low	Low-normal
Licorice ingestion syndrome	Low	Low
High-salt diet	Low	Low
Oral contraceptives	High	Normal
Cirrhosis	High	High
Malignant hypertension	High	High
Unilateral renal disease	High	High
"High-renin" essential hypertension	High	High
Pregnancy	High	High
Diuretic overuse	High	High
Juxtaglomerular tumor (Bartter's syndrome)	High	High
Low-salt diet	High	High
Addison's disease	High	Low
Hypokalemia	High	Low

SICKLE CELL TEST

Normal: Negative
Positive in: Sickle cell anemia, sickle cell trait, combination of *Hb S* gene with other disorders such as alpha-thalassemia, beta-thalassemia.

SMOOTH MUSCLE ANTIBODY

Normal: Negative
Present in: Chronic acute hepatitis (≥1:80), primary biliary cirrhosis (≤1:80), infectious mononucleosis

SODIUM (serum)

Normal range: 135-147 mEq/L (135-147 mmol/L [CF: 1; SMI: 1 mmol/L])
HYPONATREMIA
A. Sodium and water depletion (deficit hyponatremia)
   1. Loss of gastrointestinal secretions with replacement of fluid but not electrolytes
      a. Vomiting
      b. Diarrhea
      c. Tube drainage
   2. Loss from skin with replacement of fluids but not electrolytes
      a. Excessive sweating
      b. Extensive burns
   3. Loss from kidney
      a. Diuretics
      b. Chronic renal insufficiency (uremia) with acidosis
   4. Metabolic loss
      a. Starvation with acidosis
      b. Diabetic acidosis

TABLE 4-22 Semen Analysis Reference Ranges

Color	Grayish white
pH	7.3-7.8 (literature range, 7.0-7.8)
Volume	2.0-5.0 ml (literature range, 1.5-6.0 ml)
Sperm count	20-250 million/ml (literature range for upper limit varies from 100-250 million/ml)
Motility	>60% motile <3 hours after specimen is obtained (literature range, >40% to >70%)
% Normal sperm	>60% (literature range, >60% to >70%)
Viscosity	Can be poured from a pipet in droplets rather than a thick strand

From Ravel R (ed): *Clinical laboratory medicine,* ed 6, St Louis, 1995, Mosby.

5. Endocrine loss
   a. Addison's disease
   b. Sudden withdrawal of long-term steroid therapy
6. Iatrogenic loss from serous cavities
   a. Paracentesis or thoracentesis

B. Excessive water (dilution hyponatremia)
1. Excessive water administration
2. Congestive heart failure
3. Cirrhosis
4. Nephrotic syndrome
5. Hypoalbuminemia (severe)
6. Acute renal failure with oliguria

C. Inappropriate antidiuretic hormone (IADH) syndrome
D. Intracellular loss (reset osmostat syndrome)
E. False hyponatremia (actually a dilutional effect)
1. Marked hypertriglyceridemia
2. Marked hyperproteinemia
3. Severe hyperglycemia

HYPERNATREMIA

Dehydration is the most frequent overall clinical finding in hypernatremia.

1. Deficient water intake (either orally or intravenously)
2. Excess kidney water output (diabetes insipidus, osmotic diuresis)
3. Excess skin water output (excess sweating, loss from burns)
4. Excess gastrointestinal tract output (severe protracted vomiting or diarrhea without fluid therapy)
5. Accidental sodium overdose
6. High-protein tube feedings

STREPTOZYME

See ANTISTREPTOLYSIN O TITER

SUCROSE HEMOLYSIS TEST (sugar water test)

Normal: Absence of hemolysis
Positive in:
Paroxysmal nocturnal hemoglobinuria
False-positive: autoimmune hemolytic anemia, megaloblastic anemias
False-negative: may occur with use of heparin or EDTA

SUDAN III STAIN (qualitative screening for fecal fat)

Normal: Negative. Test should be preceded by diet containing 100-150 g of dietary fat/day for 1 week, avoidance of high-fiber diet, and avoidance of suppositories or oily material before specimen collection.
Positive in: Steatorrhea, use of castor oil or mineral oil droplets

SYNOVIAL FLUID ANALYSIS

Table 4-23 describes the classification and interpretation of synovial fluid analysis.

TABLE 4-23 Classification and Interpretation of Synovial Fluid Analysis

Group	Diseases	Appearance	Viscosity	Mucin Clot	WBC/mm^3	% PMN	Glucose (mg/dl) (Blood-Synovial Fluid)	Protein (g/dl)
Normal	—	Clear	↑	Firm	<200	<25	<10	<2.5
I (noninflammatory)	Osteoarthritis, aseptic necrosis, traumatic arthritis, erythema nodosum, osteochondritis dissecans	Clear, yellow (may be xanthochromic if traumatic arthritis)	↑	Firm	↑ Up to 10,000	<25	<10	<2.5
II (inflammatory)	Crystal-induced arthritis, rheumatoid arthritis, Reiter's syndrome, collagen vascular disease, psoriatic arthritis, serum sickness, rheumatic fever	Clear, yellow, turbid	↓	Friable	↑↑ Up to 100,000	40-90	<40	>2.5
III (septic)	Bacterial (staphylococcal, gonococcal, tuberculosis)	Turbid	↓/↑	Friable	↑↑↑ Up to 5 million	40-100	20-100	>2.5

↑, Elevated; ↑↑, markedly high; ↓, decreased; *PMN,* polymorphonuclear leukocytes. Note that there is considerable overlap in the numbers listed above.

5. Endocrine loss
   a. Addison's disease
   b. Sudden withdrawal of long-term steroid therapy
6. Iatrogenic loss from serous cavities
   a. Paracentesis or thoracentesis

B. Excessive water (dilution hyponatremia)
1. Excessive water administration
2. Congestive heart failure
3. Cirrhosis
4. Nephrotic syndrome
5. Hypoalbuminemia (severe)
6. Acute renal failure with oliguria

C. Inappropriate antidiuretic hormone (IADH) syndrome
D. Intracellular loss (reset osmostat syndrome)
E. False hyponatremia (actually a dilutional effect)
1. Marked hypertriglyceridemia
2. Marked hyperproteinemia
3. Severe hyperglycemia

HYPERNATREMIA

Dehydration is the most frequent overall clinical finding in hypernatremia.
1. Deficient water intake (either orally or intravenously)
2. Excess kidney water output (diabetes insipidus, osmotic diuresis)
3. Excess skin water output (excess sweating, loss from burns)
4. Excess gastrointestinal tract output (severe protracted vomiting or diarrhea without fluid therapy)
5. Accidental sodium overdose
6. High-protein tube feedings

STREPTOZYME

See ANTISTREPTOLYSIN O TITER

SUCROSE HEMOLYSIS TEST (sugar water test)

Normal: Absence of hemolysis
Positive in:
Paroxysmal nocturnal hemoglobinuria
False-positive: autoimmune hemolytic anemia, megaloblastic anemias
False-negative: may occur with use of heparin or EDTA

SUDAN III STAIN (qualitative screening for fecal fat)

Normal: Negative. Test should be preceded by diet containing 100-150 g of dietary fat/day for 1 week, avoidance of high-fiber diet, and avoidance of suppositories or oily material before specimen collection.
Positive in: Steatorrhea, use of castor oil or mineral oil droplets

SYNOVIAL FLUID ANALYSIS

Table 4-23 describes the classification and interpretation of synovial fluid analysis.

T_3 (triiodothyronine)

See Table 4-24 for T_3 abnormalities.
Normal range: 75-220 ng/dl (1.2-3.4 nmol/L [CF: 0.01536; SMI: 0.1 nmol/L])
Abnormal values:
A. Elevated in hyperthyroidism (usually earlier and to a greater extent than serum T_4).

TABLE 4-23 Classification and Interpretation of Synovial Fluid Analysis

Group	Diseases	Appearance	Viscosity	Mucin Clot	WBC/mm³	% PMN	Glucose (mg/dl) (Blood-Synovial Fluid)	Protein (g/dl)
Normal	—	Clear	↑	Firm	<200	<25	<10	<2.5
I (noninflammatory)	Osteoarthritis, aseptic necrosis, traumatic arthritis, erythema nodosum, osteochondritis dissecans	Clear, yellow (may be xanthochromic if traumatic arthritis)	↑	Firm	↑ Up to 10,000	<25	<10	<2.5
II (inflammatory)	Crystal-induced arthritis, rheumatoid arthritis, Reiter's syndrome, collagen vascular disease, psoriatic arthritis, serum sickness, rheumatic fever	Clear, yellow, turbid	↓	Friable	↑↑ Up to 100,000	40-90	<40	>2.5
III (septic)	Bacterial (staphylococcal, gonococcal, tuberculosis)	Turbid	↓/↑	Friable	↑↑↑ Up to 5 million	40-100	20-100	>2.5

↑, Elevated; ↑↑, markedly high; ↓, decreased; *PMN,* polymorphonuclear leukocytes. Note that there is considerable overlap in the numbers listed above.

TABLE 4-24 Findings in Thyroid Function Tests in Various Clinical Conditions

TRH Condition	T_4	FT_4I	T_3	FT_3I	TSH	TSI	Stimulation
Hyperthyroidism							
Graves' disease	↑	↑	↑	↑	↓	+	↓
Toxic nodular goiter	↑	↑	↑	↑	↓	–	↓
Pituitary TSH-secreting tumors	↑	↑	↑	↑	↑	–	↓
T_3 thyrotoxicosis	N	N	↑	↑	↓	+, –	↓
T_4 thyrotoxicosis	↑	↑	N	N	↓	+, –	↓
Hypothyroidism							
Primary	↓	↓	↓	↓	↑	+, –	↑
Secondary	↓	↓	↓	↓	↓ N	–	↓
Tertiary	↓	↓	↓	↓	↓, N	–	N
Peripheral unresponsiveness	↑, N	↑, N	↑, N	↑	↑, N	–	N, ↑

Reprinted from Tilton RC, Barrows A: *Clinical laboratory medicine,* St Louis, 1992, Mosby.
↑, Increased; ↓, decreased; +, – variable; *N,* normal.

B. Useful in diagnosing:
   1. T_3 hyperthyroidism (thyrotoxicosis): increased T_3, normal FTI.
   2. Toxic nodular goiter: increased T_3, normal or increased T_4.
   3. Iodine deficiency: normal T_3, possibly decreased T_4.
   4. Thyroid replacement therapy with liothyronine (Cytomel): normal T_4, increased T_3 if patient is symptomatically hyperthyroid.

Not ordered routinely but indicated when hyperthyroidism is suspected and serum-free T_4 or FTI inconclusive.

T_3 RESIN UPTAKE (T_3RU)

Normal range: 25%-35%
Abnormal values: Increased in hyperthyroidism. T_3 resin uptake (T_3RU or RT_3U) measures the percentage of free T_4 (not bound to protein); it does not measure serum T_3 concentration; T_3RU and other tests that reflect thyroid hormone binding to plasma protein are also known as *thyroid hormone-binding ratios* (THBR).

T_4, FREE (free thyroxine)

Normal range: 0.8-2.8 ng/dl
Elevated in:
Graves' disease, toxic multinodular goiter, toxic adenoma, iatrogenic and factitious causes, transient hyperthyroidism
Serum-free T_4 directly measures unbound thyroxine. Free T_4 can be measured by equilibrium dialysis (gold standard of free T_4 assays) or by immunometric techniques (influenced by serum levels of lipids, proteins, and certain drugs). The free thyroxine index (FTI) can also be easily calculated by multiplying T_4 times T_3RU and dividing the result by 100; the FTI corrects for any abnormal T_4 values secondary to protein binding: $FTI = T_4 \times T_3RU/100$.
Normal values equal 1.1 to 4.3.

T_4, SERUM T_4

Normal range: 0.8-2.8 ng/dl (10-36 pmol/L [CF: 12.87; SMI: 1 pmol/L])
Abnormal values: Serum thyroxine (T_4)
Elevated in:
1. Graves' disease
2. Toxic multinodular goiter
3. Toxic adenoma
4. Iatrogenic and factitious
5. Transient hyperthyroidism
   a. Subacute thyroiditis
   b. Hashimoto's thyroiditis
   c. Silent thyroiditis
6. Rare causes: hypersecretion of TSH (e.g., pituitary neoplasms), struma ovarii, ingestion of large amounts of iodine in a patient with preexisting thyroid hyperplasia or adenoma (Jod-Basedow phenomenon), hydatidiform mole, carcinoma of thyroid, amiodarone therapy of arrhythmias.

Serum thyroxine test measures both circulating thyroxine bound to protein (represents >99% of circulating T_4) and unbound (free) thyroxine. Values vary with protein binding; changes in the concentration of T_4 secondary to changes in thyroxine-binding globulin (TBG) can be caused by the following:

Increased TBG ($\uparrow T_4$)	*Decreased TBG ($\downarrow T_4$)*
Pregnancy	Androgens, glucocorticoids
Estrogens	Nephrotic syndrome, cirrhosis
Acute infectious hepatitis	Acromegaly
	Hypoproteinemia
Oral contraceptives	Familial
Familial	Phenytoin, ASA and other heroin, methadone, NSAIDs, high-dose penicillin, asparaginase
Fluorouracil, clofibrate	Chronic debilitating illness

To eliminate the suspected influence of protein binding on thyroxine values, two additional tests are available: T_3 resin uptake and serum free thyroxine.

TEGRETOL

See CARBAMAZEPINE and Table 4-24, under T_3 (Triiodothyronine).

TESTOSTERONE (total testosterone)

Normal range: Variable with age and sex
Serum/plasma
Males: 280-1100 ng/dl Females: 15-70 ng/dl
Urine
Males: 50-135 μg/day Females: 2-12 μg/day
Elevated in: Testicular tumors, ovarian masculinizing tumors, testosterone replacement therapy
Decreased in: Hypogonadism, sleep apnea

THEOPHYLLINE

Normal therapeutic range: 10-20 mcg/ml

THORACENTESIS FLUID

Testing and evaluation of results:
1. Pleural effusion fluid should be differentiated in exudate or transudate. The initial laboratory studies should be aimed only at distinguishing an exudate from a transudate.
   a. Tube 1: protein, LDH, albumin.
   b. Tubes 2, 3, 4: save the fluid until further notice. In selected patients with suspected empyema, a pH level may be useful (generally ≤7.0). See following for proper procedure to obtain a pH level from pleural fluid.
      NOTE: Do not order further tests until the presence of an exudate is confirmed on the basis of protein and LDH determinations (see Section III); however, if the results of protein and LDH determinations cannot be obtained within a reasonable time (resulting in unnecessary delay), additional laboratory tests should be ordered at the time of thoracentesis.
2. A serum/effusion albumin gradient of ≤1.2 g/dl is indicative of exudative effusions, especially in patients with congestive heart failure (CHF) treated with diuretics.
3. Note the appearance of the fluid:
   a. A grossly hemorrhagic effusion can be a result of a traumatic tap, neoplasm, or an embolus with infarction.
   b. A milky appearance indicates either of the following:
      (1) Chylous effusion: caused by trauma or tumor invasion of the thoracic duct; lipoprotein electrophoresis of the effusion reveals chylomicrons and triglyceride levels >115 mg/dl.
      (2) Pseudochylous effusion: often seen with chronic inflammation of the pleural space (e.g., TB, connective tissue diseases).
4. If transudate, consider CHF, cirrhosis, chronic renal failure, and other hypoproteinemic states and perform subsequent workup accordingly.
5. If exudate, consider ordering these tests on the pleural fluid:
   a. Cytologic examination for malignant cells (for suspected neoplasm).
   b. Gram stain, cultures (aerobic and anaerobic), and sensitivities (for suspected infectious process).
   c. AFB stain and cultures (for suspected TB).
   d. pH: a value <7.0 suggests parapneumonic effusion or empyema; a pleural fluid pH must be drawn anaerobically and iced immediately; the syringe should be prerinsed with 0.2 ml of 1:1000 heparin.
   e. Glucose: a low glucose level suggests parapneumonic effusions and rheumatoid arthritis.
   f. Amylase: a high amylase level suggests pancreatitis or ruptured esophagus.
   g. Perplexing pleural effusions are often a result of malignancy (e.g., lymphoma, malignant mesothelioma, ovarian carcinoma), TB, subdiaphragmatic processes, prior asbestos exposure, and postcardiac injury syndrome.

THROMBIN TIME (TT)

Normal range: 11.3-18.5 sec
Elevated in: Thrombolytic and heparin therapy, disseminated intravascular coagulation, hypofibrinogenemia, dysfibrinogenemia

THYROGLOBULIN

Normal: 3-40 ng/ml. Thyroglobulin is a tumor marker for monitoring the status of patients with papillary or follicular thyroid cancer following resection.
Elevated in: Papillary or follicular thyroid cancer, Hashimoto's thyroiditis, Graves' disease, subacute thyroiditis

THYROID MICROSOMAL ANTIBODIES

Normal: Undetectable. Low titers may be present in 5%-10% of normal individuals
Elevated in: Hashimoto's disease, thyroid carcinoma, early hypothyroidism, pernicious anemia

THYROID-STIMULATING HORMONE (TSH)

Normal range: 2-11 μU/ml (2-11 mU/L [CF: 1; SMI: 1 mU/L])
CONDITIONS THAT INCREASE SERUM THYROID-STIMULATING HORMONE VALUES
Laboratory error
Primary hypothyroidism
Synthroid therapy with insufficient dose
Lithium or amiodarone; some patients
Hashimoto's thyroiditis in later stage
Large doses of inorganic iodide (e.g., SSKI)
Severe nonthyroid illness in recovery phase
Iodine deficiency (moderate or severe)
Addison's disease
TSH specimen drawn in evening (peak of diurnal variation)
Pituitary TSH-secreting tumor
Therapy of hypothyroidism (3-6 wk after beginning therapy [range, 1-8 wk]; sometimes longer when pretherapy TSH is over 100 μU/ml)
Acute psychiatric illness
Peripheral resistance to T_4 syndrome
Antibodies (e.g., HAMA) interfering with monoclonal sandwich method of TSH assay
Telepaque (iopanoic acid) and Oragrafin (ipodate) x-ray contrast media
Amphetamines
High altitudes
CONDITIONS THAT DECREASE SERUM THYROID-STIMULATING HORMONE VALUES
Laboratory error
T_4/T_3 toxicosis (diffuse or nodular etiology)
Excessive therapy for hypothyroidism
Active thyroiditis (subacute, painless, or early active Hashimoto's disease)
Multinodular goiter containing areas of autonomy
Severe nonthyroid illness (especially acute trauma, dopamine, or glucocorticoid)
T_3 toxicosis
Pituitary insufficiency
Cushing's syndrome (and some patients on high-dose glucocorticoid)
Jod-Basedow (iodine-induced) hyperthyroidism
Thyroid-stimulating hormone drawn 2-4 hr after levothyroxine dose
Postpartum transient toxicosis
Factitious hyperthyroidism
Struma ovarii
Radioimmunoassay, surgery, or antithyroid drug therapy for hyperthyroidism 4-6 weeks (range, 2 wk to 2 yr) after the treatment
Interleukin-2 drugs (3%-6% of cases) or α-interferon therapy (1% of cases)
Hyperemesis gravidarum
Amiodarone therapy

THYROTROPIN (TSH) RECEPTOR ANTIBODIES

Normal: <130% of basal activity
Elevated in: Values between 1.3 and 2.0 are found in 10% of patients with thyroid disease other than Graves' disease. Values >2.8 have been found only in patients with Graves' disease.

THYROTROPIN RELEASING HORMONE (TRH) STIMULATION TEST

Elevated in: Celiac disease (specificity, 94%-97%; sensitivity, 90%-98%), dermatitis herpetiformis

THYROXINE (T_4)

Normal range: 4-11 μg/dl (51-142 nmol/L [CF: 12.87; SMI: 1 nmol/L])

TIBC

See IRON-BINDING CAPACITY

TISSUE TRANSGLUTAMINASE ANTIBODY

Normal: Negative
Present in: Celiac disease (specificity, 94%-97%, sensitivity, 90%-98%), dermatitis herpetiformis

TRANSFERRIN

Normal range: 170-370 mg/dl (1.7-3.7 g/L [CF: 0.01; SMI: 0.01 g/L])
Elevated in: Iron deficiency anemia, oral contraceptive administration, viral hepatitis, late pregnancy
Decreased in: Nephrotic syndrome, liver disease, hereditary deficiency, protein malnutrition, neoplasms, chronic inflammatory states, chronic illness, thalassemia, hemochromatosis, hemolytic anemia

TRIGLYCERIDES

Normal range: <150 mg/dl (<1.80 mmol/L [CF: 0.01129; SMI: 0.02 mmol/L])
Elevated in: Hyperlipoproteinemias (types I, IIb, III, IV, V), hypothyroidism, pregnancy, estrogens, acute myocardial infarction, pancreatitis, alcohol intake, nephrotic syndrome, diabetes mellitus, glycogen storage disease
Decreased in: Malnutrition, congenital abetalipoproteinemias, drugs (e.g., gemfibrozil, fenofibrate, nicotinic acid, clofibrate)

TRIIODOTHYRONINE

See T_3

TROPONINS, SERUM

Normal range: 0-0.4 ng/ml (negative). If there is clinical suspicion of evolving acute MI or ischemic episode, repeat testing in 5-6 hours is recommended.
Indeterminate: 0.05-0.49 ng/ml. Suggest further tests. In a patient with unstable angina and this troponin I level, there is an increased risk of a cardiac event in the near future.
Strong probability of acute MI:
≥0.05 ng/ml
Cardiac troponin T (CTNT) is a highly sensitive marker for myocardial injury for the first 48 hours after MI and for up to 5-7 days (see Fig. 4-2, under "Creatine Kinase Isoenzymes"). It may also be elevated in renal failure, chronic muscle disease, and trauma.
Cardiac troponin I (CTNI) is highly sensitive and specific for myocardial injury (≥CK-MB) in the initial 8 hours, peaks within 24 hours and lasts up to 7 days. With progressively higher levels of cTnI, the risk of mortality increases because the amount of necrosis increases.

TSH

See THYROID-STIMULATING HORMONE

TT

See THROMBIN TIME

TUBERCULIN TEST (PPD)

Abnormal results: see Boxes 4-3 and 4-4 for interpretation.

BOX 4-3 PPD Reaction Size Considered "Positive" (Intracutaneous 5 TU Mantoux Test at 48 hr)

5 mm or More
- HIV infection or risk factors for HIV
- Close recent contact with active TB case
- Persons with chest x-ray consistent with healed TB

10 mm or More
- Foreign-born persons from countries with high TB prevalence in Asia, Africa, and Latin America
- IV drug users
- Medically underserved low-income population groups (including Native Americans, Hispanics, and blacks)
- Residents of long-term care facilities (nursing homes, mental institutions)
- Medical conditions that increase risk for TB (silicosis, gastrectomy, undernourishment, diabetes mellitus, high-dose corticosteroids or immunosuppression Rx, leukemia or lymphoma, other malignancies)
- Employees of long-term care facilities, schools, child-care facilities, health care facilities

15 mm or More
- All others not already listed

TB, Tuberculosis; *TU,* tuberculin units.

BOX 4-4 Factors Associated with False-Negative Tuberculin Tests

Technical Errors
- Improper administration
- Inaccurate reading
- Loss of potency of antigen

Patient-Related Factors (Anergy)
- Age (elderly)
- Nutritional status
- Medications: corticosteroids, immunosuppressive agents
- Severe tuberculosis
- Coexisting diseases
  - HIV infection
  - Viral illness or vaccination
  - Lymphoreticular malignancies
  - Sarcoidosis
  - Solid tumors
  - Lepromatous leprosy
  - Sjögren's syndrome
  - Ataxia telangiectasia
  - Uremia
  - Primary biliary cirrhosis
  - Systemic lupus erythematosus
- Severe systemic disease of any etiology

Reprinted from Stein JH (ed): *Internal medicine,* ed 4, St Louis, 1994, Mosby.

UNCONJUGATED BILIRUBIN

See BILIRUBIN, DIRECT

UREA NITROGEN, BLOOD (BUN)

Normal range: 8-18 mg/dl (3-6.5 mmol/L [CF: 0.357; SMI: 0.5 mmol/L])

Box 4-5 describes factors affecting BUN level independent of renal function.

Elevated in: Drugs (aminoglycosides and other antibiotics, diuretics, lithium, corticosteroids), dehydration, gastrointestinal bleeding, decreased renal blood flow (shock, congestive heart failure, myocardial infarction), renal disease (glomerulonephritis, pyelonephritis, diabetic nephropathy), urinary tract obstruction (prostatic hypertrophy)

Decreased in: Liver disease, malnutrition, third trimester of pregnancy, overhydration, acromegaly, celiac disease

BOX 4-5 Factors Affecting Blood Urea Nitrogen Level Independent of Renal Function

Disproportionate Increase in Blood Urea Nitrogen
- Volume depletion ("prerenal azotemia")
- Gastrointestinal hemorrhage
- Corticosteroid or cytotoxic agents
- High-protein diet
- Obstructive uropathy
- Sepsis
- Catabolic states tissue breakdown

Disproportionate Decrease in Blood Urea Nitrogen
- Low-protein diet
- Liver disease

Reprinted from Andreoli TE (ed): *Cecil essentials of medicine,* ed 5, Philadelphia, 2001, WB Saunders.

URIC ACID (serum)

Normal range: 2-7 mg/dl

Elevated in: Renal failure, gout, excessive cell lysis (chemotherapeutic agents, radiation therapy, leukemia, lymphoma, hemolytic anemia), hereditary enzyme deficiency (hypoxanthine-guanine-phosphoribosyl transferase), acidosis, myeloproliferative disorders, diet high in purines or protein, drugs (diuretics, low doses of ASA, ethambutol, nicotinic acid), lead poisoning, hypothyroidism, Addison's disease, nephrogenic diabetes insipidus, active psoriasis, polycystic kidneys

Decreased in: Drugs (allopurinol, febuxostat, high doses of ASA, probenecid, warfarin, corticosteroid), deficiency of xanthine oxidase, syndrome of inappropriate antidiuretic hormone secretion, renal tubular deficits (Fanconi's syndrome), alcoholism, liver disease, diet deficient in protein or purines, Wilson's disease, hemochromatosis

URINALYSIS

Normal range:
Color: light straw
Appearance: clear
Ketones: absent
pH: 4.5-8 (average, 6)
Protein: absent
Glucose: absent
Specific gravity: 1.005-1.030
Occult blood absent
Microscopic examination:
Red blood cells: 0-5 (high-power field)
White blood cells: 0-5 (high-power field)
Bacteria (spun specimen): absent
Casts: 0-4 hyaline (low-power field)
Abnormalities in the microscopic examination of urine are described in Table 4-25.

URINE AMYLASE

Normal range: 35-260 U Somogyi/hr (6.5-48.1 U/hr [CF: 0.185; SMI: 1 U/hr])

Elevated in: Pancreatitis, carcinoma of the pancreas

URINE BILE

Normal: Absent

Abnormal:
Urine bilirubin: hepatitis (viral, toxic, drug-induced), biliary obstruction
Urine urobilinogen: hepatitis (viral, toxic, drug-induced), hemolytic jaundice, liver cell dysfunction (cirrhosis, infection, metastases)

TABLE 4-25 Microscopic Examination of the Urine

Finding	Associations
Casts	
Red blood cell	Glomerulonephritis, vasculitis
White blood cell	Interstitial nephritis, pyelonephritis
Epithelial cell	Acute tubular necrosis, interstitial nephritis, glomerulonephritis
Granular	Renal parenchymal disease (nonspecific)
Waxy, broad	Advanced renal failure
Hyaline	Normal finding in concentrated urine
Fatty	Heavy proteinuria
Cells	
Red blood cell	Urinary tract infection, urinary tract inflammation
White blood cell	Urinary tract infection, urinary tract inflammation
Eosinophil	Acute interstitial nephritis
(Squamous) epithelial cell	Contaminants
Crystals	
Uric acid	Acid urine, acute uric acid nephropathy, hyperuricosuria
Calcium phosphate	Alkaline urine
Calcium oxalate	Acid urine, hyperoxaluria, ethylene glycol poisoning
Cystine	Cystinuria
Sulfur	Sulfa-containing antibiotics

From Andreoli TE (ed): *Cecil essentials of medicine,* ed 5, Philadelphia, 2001, WB Saunders.

URINE CALCIUM

Normal range: <250 mg/24 hr (<6.2 mmol/dl [CF: 0.02495; SMI: 0.1 mmol/dl])
Elevated in: Primary hyperparathyroidism, hypervitaminosis D, bone metastases, multiple myeloma, increased calcium intake, steroids, prolonged immobilization, sarcoidosis, Paget's disease, idiopathic hypercalciuria, renal tubular acidosis
Decreased in: Hypoparathyroidism, pseudohypoparathyroidism, vitamin D deficiency, vitamin D–resistant rickets, diet low in calcium, drugs (thiazide diuretics, oral contraceptives), familial hypocalciuric hypercalcemia, renal osteodystrophy, potassium citrate therapy

URINE cAMP

Elevated in: Hypercalciuria, familial hypocalciuric hypercalcemia, primary hyperparathyroidism, pseudohypoparathyroidism, rickets
Decreased in: Vitamin D intoxication, sarcoidosis

URINE CATECHOLAMINES

Normal range:
Norepinephrine: <100 μg/24 hr (<590 nmol/day [CF: 5.911; SMI: 10 nmol/day])
Epinephrine: <10 μg/24 hr (55 nmol/day [CF: 5.458; SMI: 5 nmol/day])
Elevated in: Pheochromocytoma, neuroblastoma, severe stress

URINE CHLORIDE

Normal range: 110-250 mEq/day (110-250 mmol/day [CF: 1; SMI: 1 mmol/day])
Elevated in: Corticosteroids, Bartter's syndrome, diuretics, metabolic acidosis, severe hypokalemia
Decreased in: Chloride depletion (vomiting), colonic villous adenoma, chronic renal failure, renal tubular acidosis

URINE COPPER

Normal range: <40 μg/24 hr (<0.6 μmol/day [CF: 0.01574; SMI: 0.2 μmol/day])

URINE CORTISOL, FREE

Normal range: 10-110 μg/24 hr (30-300 nmol/day [CF: 2.759; SMI: 10 nmol/day])
Elevated: See CORTISOL, PLASMA

URINE CREATININE (24 hr)

Normal range:
Male: 0.8-1.8 g/day (7-16 mmol/day [CF: 8.840; SMI: 0.1 mmol/day])
Female: 0.6-1.6 g/day (5.3-14 mmol/day)
NOTE: Useful test as an indicator of completeness of 24-hr urine collection.

URINE CRYSTALS

Uric acid: acid urine, hyperuricosuria, uric acid nephropathy
Sulfur: antibiotics containing sulfa
Calcium oxalate: ethylene glycol poisoning, acid urine, hyperoxaluria
Calcium phosphate: alkaline urine
Cystine: cystinuria

URINE EOSINOPHILS

Normal: Absent
Present in: Interstitial nephritis, acute tubular necrosis, urinary tract infection, kidney transplant rejection, hepatorenal syndrome

URINE GLUCOSE (QUALITATIVE)

Normal: Absent
Present in: Diabetes mellitus, renal glycosuria (decreased renal threshold for glucose), glucose intolerance

URINE HEMOGLOBIN, FREE

Normal: Absent
Present in: Hemolysis (with saturation of serum haptoglobin binding capacity and renal threshold for tubular absorption of hemoglobin)

URINE HEMOSIDERIN

Normal: Absent
Present in: Paroxysmal nocturnal hemoglobinuria, chronic hemolytic anemia, hemochromatosis, blood transfusion, thalassemias

URINE 5-HYDROXYINDOLE-ACETIC ACID (URINE 5-HIAA)

Normal range: 2-8 mg/24 hr (10-40 μmol/day [CF: 5.23; SMI: 5 μmol/day])
Elevated in: Carcinoid tumors, after ingestion of certain foods (bananas, plums, tomatoes, avocados, pineapples, eggplant, walnuts), drugs (monoamine oxidase inhibitors, phenacetin, methyldopa, glycerol guaiacolate, acetaminophen, salicylates, phenothiazines, imipramine, methocarbamol, reserpine, methamphetamine)

URINE INDICAN

Normal: Absent
Present in: Malabsorption secondary to intestinal bacterial overgrowth

URINE KETONES (semiquantitative)

Normal: Absent
Present in: Diabetic ketoacidosis, alcoholic ketoacidosis, starvation, isopropanol ingestion

URINE METANEPHRINES

Normal range: 0-2.0 mg/24 hr (0-11.0 μmol/day [CF: 5.458; SMI: 0.5 μmol/day])
Elevated in: Pheochromocytoma, neuroblastoma, drugs (caffeine, phenothiazines, monoamine oxidase inhibitors), stress

URINE MYOGLOBIN

Normal: Absent
Present in: Severe trauma, hyperthermia, polymyositis/dermatomyositis, carbon monoxide poisoning, drugs (narcotic and amphetamine toxicity), hypothyroidism, muscle ischemia

URINE NITRITE

Normal: Absent
Present in: Urinary tract infections

URINE OCCULT BLOOD

Normal: Negative
Positive in: Trauma to urinary tract, renal disease (glomerulonephritis, pyelonephritis), renal or ureteral calculi, bladder lesions (carcinoma, cystitis), prostatitis, prostatic carcinoma, menstrual contamination, hematopoietic disorders (hemophilia, thrombocytopenia), anticoagulants, ASA

URINE OSMOLALITY

Normal range: 50-1200 mOsm/kg (50-1200 mmol/kg [CF: 1; SMI: 1 mmol/kg])
Elevated in: Syndrome of inappropriate antidiuretic hormone secretion, dehydration, glycosuria, adrenal insufficiency, high-protein diet
Decreased in: Diabetes insipidus, excessive water intake, IV hydration with D_5W, acute renal insufficiency, glomerulonephritis

URINE pH

Normal range: 4.6-8 (average, 6)
Elevated in: Bacteriuria, vegetarian diet, renal failure with inability to form ammonia, drugs (antibiotics, sodium bicarbonate, acetazolamide)
Decreased in: Acidosis (metabolic, respiratory), drugs (ammonium chloride, methenamine mandelate), diabetes mellitus, starvation, diarrhea

URINE PHOSPHATE

Normal range: 0.8-2.0 g/24 hr
Elevated in: Acute tubular necrosis (diuretic phase), chronic renal disease, uncontrolled diabetes mellitus, hyperparathyroidism, hypomagnesemia, metabolic acidosis, metabolic alkalosis, neurofibromatosis, adult-onset vitamin D–resistant hypophosphatemic osteomalacia
Decreased in: Acromegaly, acute renal failure, decreased dietary intake, hypoparathyroidism, respiratory acidosis

URINE POTASSIUM

Normal range: 25-100 mEq/24 hr (25-100 mmol/day [CF: 1; SMI: 1 mmol/day])
Elevated in: Aldosteronism (primary, secondary), glucocorticoids, alkalosis, renal tubular acidosis, excessive dietary potassium intake
Decreased in: Acute renal failure, potassium-sparing diuretics, diarrhea, hypokalemia

URINE PROTEIN (quantitative)

Normal range: <150 mg/24 hr (<0.15 g/day [CF: 0.001; SMI: 0.01 g/day])
Elevated in:
Nephrotic syndrome as a result of primary renal diseases
Malignant hypertension
Malignancies: multiple myeloma, leukemias, Hodgkin's disease
Congestive heart failure
Diabetes mellitus
Systemic lupus erythematosus, rheumatoid arthritis
Sickle cell disease
Goodpasture's syndrome
Malaria
Amyloidosis, sarcoidosis
Tubular lesions: cystinosis
Functional (after heavy exercise)
Pyelonephritis
Pregnancy
Constrictive pericarditis
Renal vein thrombosis
Toxic nephropathies: heavy metals, drugs
Radiation nephritis
Orthostatic (postural) proteinuria
Benign proteinuria: fever, heat or cold exposure

URINE SEDIMENT

See Fig. 4-14 for evaluation of common abnormalities.

URINE SODIUM (quantitative)

Normal range: 40-220 mEq/day (40-220 mmol/day [CF: 1; SMI: 1 mmol/day])
Elevated in: Diuretic administration, high sodium intake, salt-losing nephritis, acute tubular necrosis, vomiting, Addison's disease, syndrome of inappropriate antidiuretic hormone secretion, hypothyroidism, congestive heart failure, hepatic failure, chronic renal failure, Bartter's syndrome, glucocorticoid deficiency, interstitial nephritis caused by analgesic abuse, mannitol, dextran, or glycerol therapy, milk-alkali syndrome, decreased renin secretion, postobstructive diuresis
Decreased in: Increased aldosterone, glucocorticoid excess, hyponatremia, prerenal azotemia, decreased salt intake

URINE SPECIFIC GRAVITY

Normal range: 1.005-1.03
Elevated in: Dehydration, excessive fluid losses (vomiting, diarrhea, fever), x-ray contrast media, diabetes mellitus, congestive heart failure, syndrome of inappropriate antidiuretic hormone secretion, adrenal insufficiency, decreased fluid intake
Decreased in: Diabetes insipidus, renal disease (glomerulonephritis, pyelonephritis), excessive fluid intake or IV hydration

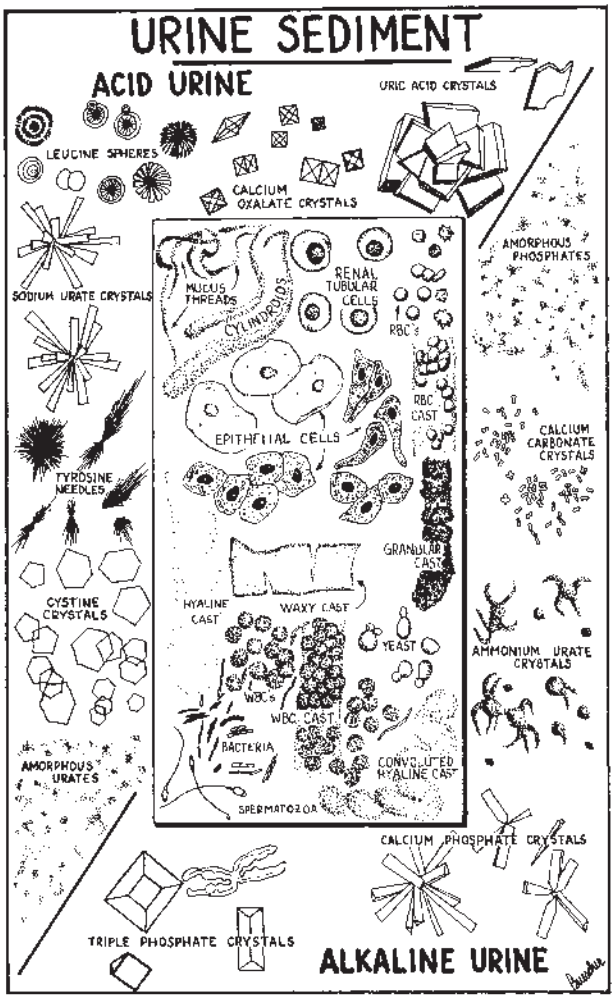

FIGURE 4-14 Microscopic examination of urinary sediment. (Reprinted from Grigorian Greene M: *The Harriet Lane handbook: a manual for pediatric house officers,* ed 17, St Louis, 2007, Mosby.)

URINE VANILLYIMANDELIC ACID (VMA)

Normal range: <6.8 mg/24 hr (<35 μmol/day [CF: 5.046; SMI: 1 μmol/day])

Elevated in: Pheochromocytoma, neuroblastoma, ganglioblastoma, drugs (isoproterenol, methocarbamol, levodopa, sulfonamides, chlorpromazine), severe stress, after ingestion of bananas, chocolate, vanilla, tea, coffee

Decreased in: Drugs (monoamine oxidase inhibitors, reserpine, guanethidine, methyldopa)

URINE VANILLYIMANDELIC ACID (VMA)

Normal range: <6.8 mg/24 hr (<35 μmol/day [CF: 5.046; SMI: 1 μmol/day])
Elevated in: Pheochromocytoma, neuroblastoma, ganglioblastoma, drugs (isoproterenol, methocarbamol, levodopa, sulfonamides, chlorpromazine), severe stress, after ingestion of bananas, chocolate, vanilla, tea, coffee
Decreased in: Drugs (monoamine oxidase inhibitors, reserpine, guanethidine, methyldopa)

VARICELLA-ZOSTER VIRUS (VZV) SEROLOGY

Test description: Test can be performed on whole blood, tissue, skin lesions, and CSF

VASOACTIVE INTESTINAL PEPTIDE (VIP)

Normal: <50 pg/ml
Elevated in: Pancreatic VIP-omas, neuroblastoma, pancreatic islet call hyperplasia, liver disease, MEN I, ganglioneuroma, ganglioneuroblastoma

VDRL

Normal range: Negative
Positive test: Syphilis, other treponemal diseases (yaws, pinta, bejel)
NOTE: A false-positive test may be seen in patients with systemic lupus erythematosus and other autoimmune diseases, infectious mononucleosis, HIV, atypical pneumonia, malaria, leprosy, typhus fever, rat-bite fever, relapsing fever.
NOTE: See Table 4-26 for interpretation of serologic tests for syphilis.

VISCOSITY (serum)

Normal range: 1.4-1.8 relative to water (1.10-1.22 centipoise)
Elevated in: Monoclonal gammopathies (Waldenström's macroglobulinemia, multiple myeloma), hyperfibrinogenemia, systemic lupus erythematosus, rheumatoid arthritis, polycythemia, leukemia

VITAMIN B_{12}

Normal:
190-900 ng/ml
Causes of vitamin B_{12} deficiency:
1. Pernicious anemia (antibodies against intrinsic factor and gastric parietal cells)
2. Dietary (strict lacto-ovovegetarians, food faddists)
3. Malabsorption (achlorhydria, gastrectomy, ileal resection, pancreatic insufficiency, drugs [omeprazole, cholestyramine])

Falsely low levels occur in patients with severe folate deficiency, in patients using high doses of ascorbic acid, and when cobalamin levels are measured after nuclear medicine studies (radioactivity interferes with cobalamin radioimmunoassay).
Falsely high or normal levels in patients with cobalamin deficiency can occur in severe liver disease and chronic granulocytic leukemia.
The absence of anemia or macrocytosis does not exclude the diagnosis of cobalamin deficiency.

VITAMIN D, 1,25 DIHYDROXY CALCIFEROL

Normal: 16-65 pg/ml
Elevated in: Tumor calcinosis, primary hyperparathyroidism, sarcoidosis, tuberculosis, idiopathic hypercalciuria
Decreased in: Postmenopausal osteoporosis, chronic renal failure, hypoparathyroidism, tumor-induced osteomalacia, rickets, tumor-induced osteomalacia, elevated blood lead levels

VITAMIN K

Normal: 0.10-2.20 ng/ml
Decreased in: Primary biliary cirrhosis, anticoagulants, antibiotics, choelstyramine, GI disease, pancreatic disease, cystic fibrosis, obstructive jaundice, hypoprothrombinemia, hemorrhagic disease of the newborn

TABLE 4-26 Interpretation of Serologic Tests for Syphilis*

Nontreponemal Tests	Treponemal Tests	Interpretation of Finding: Is Syphilis Present?*
Nonreactive	Nonreactive	Early primary syphilis is not ruled out by negative serologic tests. Early syphilis is present in 13%-30% of patients who have a negative microhemagglutination *Treponema pallidum* test; in about 30% of patients who present with chancre but have a nonreactive reagin test; and in about 10% of patients who have a negative FTA-ABS test. Late syphilis is present in a very small fraction of patients. Adequately treated syphilis in remote past may produce these results, but treponemal tests usually remain reactive.
	Reactive	Observed in about 10% of patients with chancre. The treponemal tests may turn positive shortly before the reagin tests. Reagin tests repeated after several days are generally positive. In adequately treated early syphilis, the reagin test may return to nonreactive within 1-2 yr, whereas the treponemal tests generally do not. Late syphilis is not ruled out by a negative reagin test. The sensitivity of the reagin tests is lower than that of treponemal tests in untreated late syphilis. In secondary syphilis, rarely, a highly reactive serum appears negative when tested undiluted with a regain test because flocculation is inhibited by relative antibody excess. Not reported to occur with treponemal tests. Quantitative reagin tests are positive. False-positive treponemal tests occur in 40% of patients with Lyme disease.
Reactive	Nonreactive borderline (FTA-ABS)	Finding is not diagnostic of syphilis but constitutes a classic biologic false-positive reaction. Not diagnostic of syphilis; most patients (90%) with this pattern do not develop clinical or serologic evidence of syphilis. Repeat test is indicated. Chronic borderline results are associated with a variety of conditions other than syphilis.
	Beaded (FTA-ABS)	Not diagnostic of syphilis. Seen with collagen vascular disease.
	Reactive	Findings diagnostic of syphilis or other treponemal disease. In adequately treated syphilis, one would expect (1) a sustained fourfold drop in titer of reagin test, although reagin test may remain positive after adequate therapy; (2) treponemal tests remain positive after adequate therapy. Concurrent false-positive results on both nontreponemal and treponemal tests could occur in rare instances. It may be impossible to rule out syphilis in an individual with this test profile.

Reprinted from Stein JH (ed): *Internal medicine,* ed 4, St Louis, 1994, Mosby.
FTA-ABS, Fluorescent treponemal antibody, absorbed.
*Serologic data must always be interpreted in the light of a total clinical evaluation. Diagnosis based on serologic criteria alone is fraught with error. Serologic tests apparently in conflict with clinical diagnosis should be confirmed by repetition or possibly referral to a reference laboratory.

VON WILLEBRAND FACTOR

Normal: Levels vary according to blood type; blood type O: 50-150 U/dl; blood type non-O: 90-200 U/dl

Decreased in: von Willebrand's disease (however, in type II von Willebrand's disease the antigen may be normal but the function is impaired)

VON WILLEBRAND FACTOR

Normal: Levels vary according to blood type; blood type O: 50-150 U/dl; blood type non-O: 90-200 U/dl

Decreased in: von Willebrand's disease (however, in type II von Willebrand's disease the antigen may be normal but the function is impaired)

PART C
GUIDE TO CLINICAL PREVENTIVE SERVICES

Age-Specific Charts

TABLE 5-1 Birth to 10 Years

Interventions considered and recommended for the Periodic Health Examination

Leading causes of death
- Conditions originating in perinatal period
- Congenital anomalies
- Sudden infant death syndrome
- Unintentional injuries (non–motor vehicle)
- Motor vehicle injuries

INTERVENTIONS FOR THE GENERAL POPULATION

Screening
- Height and weight
- Blood pressure
- Vision screen (ages 3-4 yr)
- Hemoglobinopathy screen (birth)[1]
- Phenylalanine level (birth)[2]
- Thyroxine and/or thyroid-stimulating hormone (birth)[3]

Counseling

Injury prevention
- Child safety car seats (age <5 yr)
- Lap/shoulder belts (age ≥5 yr)
- Bicycle helmet; avoid bicycling near traffic
- Smoke detector, flame-retardant sleepwear
- Hot water heater temperature <120°-130° F
- Window/stair guards, pool fence
- Safe storage of drugs, toxic substances, firearms, and matches
- Syrup of ipecac, poison control phone number
- CPR training for parents/caretakers

Diet and exercise
- Breastfeeding, iron-enriched formula and foods (infants and toddlers)
- Limit fat and cholesterol; maintain caloric balance; emphasize grains, fruits, vegetables (age ≥2 yr)
- Regular physical activity*

Substance use
- Effects of passive smoking*
- Antitobacco message*

Dental health
- Regular visits to dental care provider*
- Floss, brush with fluoride toothpaste daily*
- Advice about baby bottle tooth decay*

Immunizations
- Diphtheria-tetanus-pertussis (DTaP)[4]
- Inactivated poliovirus vaccine (IPV)[5]
- Measles-mumps-rubella (MMR)[6]
- *H. influenzae* type b (Hib) conjugate[7]
- Hepatitis A vaccine (HR4)
- Hepatitis B[8]
- Varicella[9]
- Pneumococcal vaccine[10]
- Influenza[11]
- Meningococcal conjugate vaccine (MCV)[12]
- Rotavirus (RV)[13]
- Human papillomavirus vaccine (HPV)[14]

Chemoprophylaxis
- Ocular prophylaxis (birth)

INTERVENTIONS FOR HIGH-RISK POPULATIONS

Population	*Potential Interventions (see detailed high-risk definitions)*
Preterm or low birth weight	Hemoglobin/hematocrit (HR1)
Infants of mothers at risk for HIV	HIV testing (HR2)
Low income; immigrants	Hemoglobin/hematocrit (HR1); PPD (HR3)
TB contacts	PPD (HR3)
Native American/Alaska Native	Hemoglobin/hematocrit (HR1); PPD (HR3); pneumococcal vaccine (HR5)
Residents of long-term care facilities	PPD (HR3); hepatitis A vaccine (HR4); influenza vaccine (HR6)
Certain chronic medical conditions	PPD (HR3); pneumococcal vaccine (HR5); influenza vaccine (HR6)
Increased individual or community lead exposure	Blood lead level (HR7)
Inadequate water fluoridation	Daily fluoride supplement (HR8)
Family history of skin cancer; nevi; fair skin, eyes, hair	Avoid excess/midday sun, use protective clothing* (HR9)

HR, High risk; *PPD,* purified protein derivative; *TB,* tuberculosis.

[1]Whether screening should be universal or targeted to high-risk groups depends on the proportion of high-risk individuals in the screening area and other considerations. [2]If done during first 24 hr of life, repeat by age 2 wk. [3]Optimally between day 2 and 6, but in all cases before newborn nursery discharge. [4]2, 4, 6, and 12-18 mo; once between age 4-6 yr. [5]2, 4, 6-18 mo; once between age 4-6 yr. [6]12-15 mo and 4-6 yr. [7]2, 4, 6 and 12-15 mo; no dose needed at 6 mo if PRP-OMP vaccine is used for first 2 doses. [8]Birth, 1 mo, 6 mo; or, 0-2 mo, 1-2 mo later, and 6-18 mo. If not done in infancy: current visit, and 1 and 6 mo later. [9]12-18 mo; or any child without history of chickenpox or previous immunization. Include information on risk in adulthood, duration of immunity, and potential need for booster doses. Administer a second dose of varicella vaccine at age 4-6 yr. [10]Pneumococcal polysaccharide vaccine (PPSV) can be administered at the same time as the other childhood vaccines at a separate site. [11]Influenza vaccine is recommended in children 6 mo-18 yr of age. [12]Administer meningococcal conjugate vaccine (MCV) to children aged 2 through 10 yr with terminal complement component deficiency, anatomic or functional asplenia, and certain other high risk groups (see *MMWR* 54[RR-7], 2005). Persons who received MPSV 3 or more years previously and who remain at increased risk for meningococcal disease should be revaccinated with MCV. [13]Administer first dose at 2 mo. If Rotarix® is administered at ages 2 and 4 mo, a dose at 6 mo is not indicated.[14]HPV4 may be administered in a 3-dose series to males aged 9 through 26 yr and females aged 11 to 26 yr to reduce the likelihood of acquiring genital warts.

*The ability of clinician counseling to influence this behavior is unproven.

HR1: Infants aged 6-12 mo who are living in poverty, black, Native American or Alaska Native, immigrants from developing countries, preterm and low-birth-weight infants, infants whose principal dietary intake is unfortified cow's milk.

HR2: Infants born to high-risk mothers whose HIV status is unknown. Women at high risk include past or present injection drug users; persons who exchange sex for money or drugs and their sex partners; injection drug–using, bisexual, or HIV-positive sex partners currently or in past; persons seeking treatment for STDs; persons who received a blood transfusion between 1978 and 1985.

HR3: Persons infected with HIV, close contacts of persons with known or suspected TB, persons with medical risk factors associated with TB, immigrants from countries with high TB prevalence, medically underserved low-income populations (including homeless), residents of long-term care facilities.

HR4: Hepatitis A vaccine (Hep A) is recommended for all children at 1 yr of age (i.e., 12-23 mo). The two doses in the series should be administered at least 6 mo apart. Children who are not vaccinated by 2 yr of age can be vaccinated at subsequent visits.

HR5: Immunocompetent persons $\geq$2 yr with certain medical conditions, including chronic cardiac or pulmonary disease, diabetes mellitus, and anatomic asplenia, as well as cochlear implant candidates and recipients. Immunocompetent persons $\geq$2 yr living in high-risk environments or social settings (e.g., certain Native American and Alaska Native populations).

HR6: Annual vaccinations of children $\geq$6 mo who are residents of chronic care facilities or who have chronic cardiopulmonary disorders, metabolic diseases (including diabetes mellitus), hemoglobinopathies, immunosuppression, or renal dysfunction.

HR7: Children approximately age 12 mo who (1) live in communities in which the prevalence of lead levels requiring individual intervention, including residential lead hazard control or chelation, is high or undefined; (2) live in or frequently visit a home built before 1950 with dilapidated paint or with recent or ongoing renovation or remodeling; (3) have close contact with a person who has an elevated lead level; (4) live near lead industry or heavy traffic; (5) live with someone whose job or hobby involves lead exposure; (6) use lead-based pottery; or (7) take traditional ethnic remedies that contain lead.

HR8: Children living in areas with inadequate water fluoridation ($<$0.6 ppm).

HR9: Persons with a family history of skin cancer; a large number of moles; atypical moles; poor tanning ability; or light skin, hair, and eye color.

TABLE 5-2 Ages 11 to 24 Years

Interventions considered and recommended for the Periodic Health Examination

Leading causes of death
- Motor vehicle accidents/other unintentional injuries
- Homicide
- Suicide
- Malignant neoplasms
- Heart diseases

INTERVENTIONS FOR THE GENERAL POPULATION

Screening
- Height and weight
- Blood pressure[1]
- Papanicolaou (Pap) test[2] (females)
- *Chlamydia* screen[3] (females <25 yr)
- HIV screening
- Lipid panel (in high-risk young adults only)
- Rubella serology or vaccination history[4] (females >12 yr)
- Assess for problem drinking

Counseling

Injury prevention
- Lap/shoulder belts
- Bicycle/motorcycle/ATV helmets*
- Smoke detector*
- Safe storage/removal of firearms*

Substance use
- Avoid tobacco use
- Avoid underage drinking and illicit drug use*
- Avoid alcohol/drug use while driving, swimming, boating, etc.*

Sexual behavior
- STD prevention: abstinence*; avoid high-risk behavior*; condoms/female barrier with spermicide*
- Unintended pregnancy: contraception

Diet and exercise
- Limit fat and cholesterol; maintain caloric balance; emphasize grains, fruits, vegetables
- Adequate calcium intake (females)
- Regular physical activity*

Dental health
- Regular visits to dental care provider*
- Floss, brush with fluoride toothpaste daily

Immunizations
- Tetanus, diphtheria, pertussis†
- Hepatitis B[5]
- Measles-mumps-rubella (MMR) (11-12 yr)[6]
- Varicella (11-12 yr)[7]
- Rubella (females >12 yr)[4]
- Meningococcal[8]
- Human papilloma virus (females 11-26 yr, males 9-26 yr)[9]
- Influenza[10]
- Pneumococcal polysaccharide vaccine (PPSV)[11]

Chemoprophylaxis
- Multivitamin with folic acid (females)

INTERVENTIONS FOR HIGH-RISK POPULATIONS

Population	*Potential Interventions (see detailed high-risk definitions)*
High-risk sexual behavior	RPR/VDRL (HR1); screen for gonorrhea (female) (HR2), HIV (HR3), chlamydia (female) (HR4); hepatitis A vaccine (HR5)
Injection or street drug use	RPR/VDRL (HR1); HIV screen (HR3); hepatitis A vaccine (HR5); PPD (HR6); advice to reduce infection risk (HR7)
TB contacts; immigrants; low income	PPD (HR6)
Native Americans/Alaska Natives	Hepatitis A vaccine (HR5); PPD (HR6); pneumococcal vaccine (HR8)
Travelers to developing countries	Hepatitis A vaccine (HR5)
Certain chronic medical conditions	PPD (HR6); pneumococcal vaccine (HR8); influenza vaccine (HR9)
Settings where adolescents and young adults congregate	Second MMR (HR10)
Susceptible to varicella, measles, mumps	Varicella vaccine (HR11); MMR (HR12)
Blood transfusion between 1975 and 1985	HIV screen (HR3)
Institutionalized persons; health care/lab workers	Hepatitis A vaccine (HR5); PPD (HR6); influenza vaccine (HR9)
Family history of skin cancer; nevi; fair skin, eyes, hair	Avoid excess/midday sun, use protective clothing* (HR13)
Prior pregnancy with neural tube defect	Folic acid 4.0 mg (HR14)
Inadequate water fluoridation	Daily fluoride supplement (HR15)
Pregnancy	HIV screen

ATV, All-terrain vehicle; *HR,* high risk; *PPD,* purified protein derivative; *RPR,* rapid plasmin reagin; *STD,* sexually transmitted disease; *TB,* tuberculosis; *VDRL,* Venereal Disease Research Laboratory.

[1]Periodic blood pressure for persons aged ≥21 yr. [2]If sexually active at present or in the past: q ≤3 yr. If sexual history is unreliable, begin Pap tests at age 21 yr. [3]If sexually active. [4]Serologic testing, documented vaccination history, and routine vaccination against rubella (preferably with MMR) are equally acceptable alternatives. [5]If not previously immunized: current visit and 1 and 6 mo later. [6]If no previous second dose of MMR. [7]If susceptible to chickenpox. [8]Meningococcal conjugate vaccine (MCV) can be administered at 11-12 yr visit, at high school entry, or at beginning of college (especially indicated in students living in college dormitories). [9]Quadrivalent human papillomavirus (types 6, 11, 16, 18) recombinant vaccine (Gardasil) should be given to all females aged 11-26 yr who have not been previously vaccinated. The vaccine is indicated for the prevention of cervical cancer and genital warts caused by the human papilloma virus (HPV) 6, 11, 16, or 18. Gardasil is an intramuscular injection for administration to the thigh or upper arm. The schedule consists of three 0.5-ml doses, with the second dose given 2 mo after the first, and the final dose administered 6 mo after the initial dose. HPV4 may also be administered in a 3-dose series to males aged 9 through 26 years to reduce their likelihood of acquiring genital warts. [10]Influenza vaccine is recommended for children 6 mo to 18 yr of age. [11]Administer to children with certain underlying medical conditions (see *MMWR* 46[RR-8], 1997), including a cochlear implant. A single revaccination should be administered to children with functional or anatomic asplenia or other immunocompromising condition after 5 yr.

*The ability of clinician counseling to influence this behavior is unproven.

†Tdap vaccine is recommended for adolescents aged 11-12 yr who have completed the recommended childhood DTP/DTaP vaccination series and have not received a Td booster dose. Adolescents aged 13-18 yr who missed the 11- 12-yr Td/Tdap booster dose should also receive a single dose of Tdap if they have completed the recommended childhood DTP/DTaP vaccination series. A 5-yr interval from the last Td dose is encouraged when Tdap is used as a booster drug; however, a shorter interval may be used if pertussis immunity is needed.

HR1: Persons who exchange sex for money or drugs and their sex partners, persons with other STDs (including HIV), and sexual contacts of persons with active syphilis. Clinicians should also consider local epidemiology.

HR2: Females who have had two or more sex partners in the last year or a sex partner with multiple sexual contacts; exchanged sex for money or drugs; or have a history of repeated episodes of gonorrhea. Clinicians should also consider local epidemiology.

HR3: Males who had sex with males after 1975; past or present injection drug users; persons who exchange sex for money or drugs and their sex partners; injection drug–using, bisexual, or HIV-positive sex partner currently or in the past; recipients of a blood transfusion between 1978 and 1985; persons seeking treatment for STDs. Clinicians should also consider local epidemiology and screening for HIV in general population.

HR4: Sexually active females with multiple risk factors, including history of prior STD, new or multiple sex partners, age $<$25 yr, nonuse or inconsistent use of barrier contraceptives, or cervical ectopy. Clinicians should consider local epidemiology of the disease in identifying other high-risk groups.

HR5: Persons living in, traveling to, or working in areas where the disease is endemic and where periodic outbreaks occur (e.g., countries with high or intermediate endemicity; certain Alaska Native, Pacific Island, Native American, and religious communities); men who have sex with men; injection or street drug users; persons with clotting factor disorders or chronic liver disease. Vaccine may be considered for institutionalized persons and workers in these institutions; military personnel; and day-care, hospital, and laboratory workers. Clinicians should also consider local epidemiology.

HR6: HIV-positive, close contacts of persons with known or suspected TB, health care workers, persons with medical risk factors associated with TB, immigrants from countries with high TB prevalence, medically underserved low-income populations (including homeless), alcoholics, injection drug users, and residents of long-term care facilities.

HR7: Persons who continue to inject drugs.

HR8: Immunocompetent persons with certain medical conditions, including chronic cardiac or pulmonary disease, diabetes mellitus, cochlear implants candidates and recipients, and anatomic asplenia. Immunocompetent persons who live in high-risk environments or social settings (e.g., certain Native American and Alaska Native populations).

HR9: Annual vaccination of residents of chronic care facilities; persons with chronic cardiopulmonary disorders, metabolic diseases (including diabetes mellitus), hemoglobinopathies, immunosuppression, or renal dysfunction; and health care providers for high-risk patients.

HR10: Adolescents and young adults in settings where such individuals congregate (e.g., high schools and colleges) if they have not previously received a second dose.

HR11: Healthy persons aged $\geq$13 yr without a history of chickenpox or previous immunization. Consider serologic testing for presumed susceptible persons aged $\geq$13 yr.

HR12: Persons born after 1956 who lack evidence of immunity to measles or mumps (e.g., documented receipt of live vaccine on or after the first birthday, laboratory evidence of immunity, or a history of physician-diagnosed measles or mumps).

HR13: Persons with a family or personal history of skin cancer; a large number of moles; atypical moles; poor tanning ability; or light skin, hair, and eye color.

HR14: Women with prior pregnancy affected by neural tube defect who are planning pregnancy.

HR15: Persons aged $<$17 yr living in areas with inadequate water fluoridation ($<$0.6 ppm).

TABLE 5-3 Ages 25 to 64 Years

Interventions considered and recommended for the Periodic Health Examination

Leading causes of death
- Malignant neoplasms
- Heart diseases
- Motor vehicle and other unintentional injuries
- HIV infection
- Suicide and homicide

INTERVENTIONS FOR THE GENERAL POPULATION

Screening
- Blood pressure
- Height and weight
- Lipid panel (men aged 35-64 yr, women aged 45-64 yr)
- HIV screening
- Papanicolaou (Pap) test (women)[1]
- Fecal occult blood test[2] and/or colonoscopy (≥50 yr)
- Mammogram ± clinical breast examination[3] (women 40-69 yr)
- Bone density scan in postmenopausal women
- Assess for problem drinking
- Rubella serology or vaccination history[4] (women of childbearing age)

Counseling

Substance use
- Tobacco cessation
- Avoid alcohol/drug use while driving, swimming, boating, etc.*

Diet and exercise
- Limit fat and cholesterol; maintain caloric balance; emphasize grains, fruits, vegetables
- Adequate calcium intake (women)
- Regular physical activity*

Injury prevention
- Lap/shoulder belts
- Motorcycle/bicycle/ATV helmets*
- Smoke detector*
- Safe storage/removal of firearms*

Sexual behavior
- STD prevention: avoid high-risk behavior*; condoms/female barrier with spermicide*
- Unintended pregnancy: contraception

Dental health
- Regular visits to dental care provider*
- Floss, brush with fluoride toothpaste daily*

Immunizations
- Tetanus-diphtheria (Td) boosters
- Rubella[4] (women of childbearing age)
- Influenza vaccine†
- Human papilloma virus[5]
- Herpes zoster (≥60 yr)[6]

Chemoprophylaxis
- Multivitamin with folic acid (women planning or capable of pregnancy)

INTERVENTIONS FOR HIGH-RISK POPULATIONS

Population	*Potential Interventions (see detailed high-risk definitions)*
High-risk sexual behavior	RPR/VDRL (HR1); screen for gonorrhea (female) (HR2), HIV (HR3), Chlamydia (female) (HR4); hepatitis B vaccine (HR5); hepatitis A vaccine (HR6)
Injection or street drug use	RPR/VDRL (HR1); HIV screen (HR3); hepatitis B vaccine (HR5); hepatitis A vaccine (HR6); PPD (HR7); advice to reduce infection risk (HR8)
Low income; TB contacts; immigrants; alcoholics	PPD (HR7)
Native Americans/Alaska Natives	Hepatitis A vaccine (HR6); PPD (HR7); pneumococcal vaccine (HR9)
Travelers to developing countries	Hepatitis B vaccine (HR5); hepatitis A vaccine (HR6)
Certain chronic medical conditions	PPD (HR7); pneumococcal vaccine (HR9); influenza vaccine (HR10)
Blood product recipients	HIV screen (HR3); hepatitis B vaccine (HR5); hepatitis C screen
Susceptible to measles, mumps, or varicella	MMR (HR11); varicella vaccine (HR12)
Institutionalized persons	Hepatitis A vaccine (HR6); PPD (HR7); pneumococcal vaccine (HR9); influenza vaccine (HR10)
Health care/lab workers	Hepatitis B vaccine (HR5); hepatitis A vaccine (HR6); PPD (HR7); influenza vaccine (HR10)
Family history of skin cancer; fair skin, eyes, hair	Avoid excess/midday sun, use protective clothing* (HR13)
Previous pregnancy with neural tube defect	Folic acid 4.0 mg (HR14)
Cardiovascular risk factors	Lipid panel (HR 15)
Pregnancy	HIV screen

ATV, All-terrain vehicle; *HR,* high risk; *MMR,* measles-mumps-rubella; *PPD,* purified protein derivative; *RPR,* rapid plasma reagin; *STD,* sexually transmitted disease; *TB,* tuberculosis; *VDRL,* Venereal Disease Research Laboratory.

[1]Women who are or have been sexually active and who have a cervix: q ≤3 yr. Routine pap smear screening is unnecessary for women who have undergone a complete hysterectomy for benign disease. The American College of Obstetricians and Gynecologists (ACOG) recommends routine paps should start at age 21. Women 30 and older should wait 3 yrs between paps once they have had three consecutive clear tests. [2]Annually. [3]Mammogram q1-2 yr, or mammogram q1-2 yr with annual clinical breast examination. [4]Serologic testing, documented vaccination history, and routine vaccination (preferably with MMR) are equally acceptable. [5]Quadrivalent human papillomavirus (types 6, 11, 16, 18) recombinant vaccine (Gardasil) should be given to all females aged 9-26 yr who have not been previously vaccinated. The vaccine is indicated for the prevention of cervical cancer and genital warts caused by the human papilloma virus (HPV) 6, 11, 16, or 18. Gardasil is an intramuscular injection for administration to the thigh or upper arm. The schedule consists of three 0.5-ml doses, with the second dose given 2 mo after the first, and the final dose administered 6 mo after the initial dose. Gardasil is also indicated in males aged 9 to 26 yr for prevention of genital warts. [6]Herpes zoster vaccine (Zostavax) is indicated for prevention of herpes zoster (shingles) in individuals 60 yr or older. Zostavax is administered as a single dose subcutaneously. It is a lyophilic preparation of the Oka/Merck strain of live, attenuated varicella zoster virus (VZV). It should not be administered to individuals with a history of primary or acquired immunodeficiency states, persons on immunosuppressive therapy (including high-dose corticosteroids), those with active untreated tuberculosis, and those who may be pregnant.

*The ability of clinician counseling to influence this behavior is unproven.

†A live attenuated influenza vaccine (LAIV, Flumist) administered intranasally is available for healthy persons aged 2 to 49 yr.

HR1: Persons who exchange sex for money or drugs and their sex partners, persons with other STDs (including HIV), and sexual contacts of persons with active syphilis. Clinicians should also consider local epidemiology.

HR2: Women who exchange sex for money or drugs or who have had repeated episodes of gonorrhea. Clinicians should also consider local epidemiology.

HR3: Men who had sex with men after 1975; past or present injection drug users; persons who exchange sex for money or drugs and their sex partners; persons with current or past injection drug–using, bisexual, or HIV-positive sex partners; recipients of a blood transfusion between 1978 and 1985; persons seeking treatment for STDs. Clinicians should also consider local epidemiology and HIV screening in the general population.

HR4: Sexually active women with multiple risk factors, including history of STD, new or multiple sex partners, nonuse or inconsistent use of barrier contraceptives, or cervical ectopy. Clinicians should also consider local epidemiology.

HR5: Blood product recipients (including hemodialysis patients), persons with frequent occupational exposure to blood or blood products, men who have sex with men, injection drug users and their sex partners, persons with multiple recent sex partners, persons with other STDs (including HIV), travelers to countries with endemic hepatitis B.

HR6: Persons living in, traveling to, or working in areas where the disease is endemic and where periodic outbreaks occur (e.g., countries with high or intermediate endemicity; certain Alaska Native, Pacific Island, Native American, and religious communities); men who have sex with men; injection or street drug users; patients with clotting factor disorders or chronic liver disease. Consider for institutionalized persons and workers in these institutions; military personnel; and day-care, hospital, and laboratory workers. Clinicians should also consider local epidemiology.

HR7: HIV-positive, close contacts of persons with known or suspected TB, health care workers, persons with medical risk factors associated with TB, immigrants from countries with high TB prevalence, medically underserved low-income populations (including homeless), alcoholics, injection drug users, and residents of long-term care facilities.

HR8: Persons who continue to inject drugs.

HR9: Immunocompetent institutionalized persons aged $\geq$50 yr and immunocompetent persons with certain medical conditions, including chronic cardiac or pulmonary disease, anatomic asplenia, or diabetes mellitus; cochlear implant candidates and recipients. Immunocompetent persons who live in high-risk environments or social settings (e.g., certain Native American and Alaska Native populations).

HR10: Annual vaccination of residents of long-term care facilities; persons with chronic cardiopulmonary disorders, metabolic diseases (including diabetes mellitus), hemoglobinopathies, immunosuppression, or renal dysfunction; and health care providers of high-risk patients.

HR11: Persons born after 1956 who lack evidence of immunity to measles or mumps (e.g., documented receipt of live vaccine on or after the first birthday, laboratory evidence of immunity, or a history of physician-diagnosed measles or mumps).

HR12: Healthy adults without a history of chickenpox or previous immunization. Consider serologic testing for presumed susceptible adults.

HR13: Persons with a family or personal history of skin cancer; a large number of moles; atypical moles; poor tanning ability; or light skin, hair, and eye color.

HR14: Women with previous pregnancy affected by neural tube disorder who are planning pregnancy.

HR15: Clinicians should consider a fasting serum lipid panel on a case-by-case basis.

TABLE 5-4 Ages 65 and Older

Interventions considered and recommended for the Periodic Health Examination

Leading causes of death
- Heart diseases
- Malignant neoplasms (lung, colorectal, breast)
- Cerebrovascular disease
- Chronic obstructive pulmonary disease
- Pneumonia and influenza

INTERVENTIONS FOR THE GENERAL POPULATION

Screening
- Blood pressure
- Height and weight
- Fecal occult blood test[1] and/or colonoscopy
- Mammogram ± clinical breast examination[2] (women ≤69 yr)
- Papanicolaou (Pap) test (women)[3]
- Bone density scan in postmenopausal patients
- Vision screening
- Assess for hearing impairment
- Assess for problem drinking
- Offer HIV screen

Counseling

Substance use
- Tobacco cessation
- Avoid alcohol/drug use while driving, swimming, boating, etc.*

Diet and exercise
- Limit fat and cholesterol; maintain caloric balance; emphasize grains, fruits, vegetables
- Adequate calcium intake (women)
- Regular physical activity*

Injury prevention
- Lap/shoulder belts
- Motorcycle and bicycle helmets*
- Fall prevention*
- Safe storage/removal of firearms*
- Smoke detector*
- Set hot water heater to <120°-130° F
- CPR training for household members

Dental health
- Regular visits to dental care provider*
- Floss, brush with fluoride toothpaste daily*

Sexual behavior
- STD prevention: avoid high-risk sexual behavior*; use condoms

Immunizations
- Pneumococcal vaccine
- Influenza[1]
- Tetanus-diphtheria (Td) boosters
- Herpes zoster[4]

INTERVENTIONS FOR HIGH-RISK POPULATIONS

Population	*Potential Interventions (see detailed high-risk definitions)*
Institutionalized persons	PPD (HR1); hepatitis A vaccine (HR2); amantadine/rimantadine (HR4)
Chronic medical conditions; TB contacts; low income; immigrants; alcoholics	PPD (HR1)
Persons ≥75 yr or ≥70 yr with risk factors for falls	Fall prevention intervention (HR5)
Cardiovascular disease risk factors	Consider lipid screening (HR6)
Family history of skin cancer; nevi; fair skin, eyes, hair	Avoid excess/midday sun, use protective clothing* (HR7)
Native Americans/Alaska Natives	PPD (HR1); hepatitis A vaccine (HR2)
Travelers to developing countries	Hepatitis A vaccine (HR2); hepatitis B vaccine (HR8)
Blood product recipients	HIV screen (HR3); hepatitis B vaccine (HR8)
High-risk sexual behavior	Hepatitis A vaccine (HR2); HIV screen (HR3); hepatitis B vaccine (HR8); RPR/VDRL (HR9)
Injection or street drug use	PPD (HR1); hepatitis A vaccine (HR2); HIV screen (HR3); hepatitis B vaccine (HR8); RPR/VDRL (HR9); advice to reduce infection risk (HR10)
Health care/lab workers	PPD (HR1); hepatitis A vaccine (HR2); amantadine/rimantadine (HR4); hepatitis B vaccine (HR8)
Persons susceptible to varicella	Varicella vaccine (HR11)
Men aged 65 to 75 who have ever smoked	Ultrasound of abdominal aorta (HR12)

HR, High risk; *PPD,* purified protein derivative; *RPR,* rapid plasma reagin; *STD,* sexually transmitted disease; *TB,* tuberculosis; *VDRL,* Venereal Disease Research Laboratory.

[1]Annually. [2]Mammogram q1-2 yr, or mammogram q1-2 yr with annual clinical breast exam. [3]All women who are or have been sexually active and who have a cervix. Consider discontinuation of testing after age 65 yr if previous regular screening with consistently normal results. [4]Herpes zoster vaccine (Zostavax) is indicated for prevention of herpes zoster (shingles) in individuals age ≥60 yr. Zostavax is administered as a single dose subcutaneously. It is a lyophilic preparation of the Oka/Merck strain of live, attenuated varicella zoster virus (VZV). It should not be administered to individuals with a history of primary or acquired immunodeficiency states, persons on immunosuppressive therapy (including high-dose corticosteroids), those with active untreated tuberculosis, and those who may be pregnant.

*The ability of clinician counseling to influence this behavior is unproven.

HR1: HIV-positive, close contacts of persons with known or suspected TB, health care workers, persons with medical risk factors associated with TB, immigrants from countries with high TB prevalence, medically underserved low-income populations (including homeless), alcoholics, injection drug users, and residents of long-term care facilities.

HR2: Persons living in, traveling to, or working in areas where the disease is endemic and where periodic outbreaks occur (e.g., countries with high or intermediate endemicity; certain Alaska Native, Pacific Island, Native American, and religious communities); men who have sex with men; injection or street drug users; persons with clotting factor disorders or chronic liver disease. Consider for institutionalized persons and workers in these institutions and day-care, hospital, and laboratory workers. Clinicians should also consider local epidemiology and HIV screening in the general population.

HR3: Men who had sex with men after 1975; past or present injection drug users; persons who exchange sex for money or drugs and their sex partners; persons with current or past injection drug–using, bisexual, or HIV-positive sex partners; recipients of a blood transfusion between 1978 and 1985; persons seeking treatment for STDs. Clinicians should also consider local epidemiology.

HR4: Consider for persons who have not received influenza vaccine or are vaccinated late, when the vaccine may be ineffective because of major antigenic changes in the virus; for unvaccinated persons who provide home care for high-risk persons; as supplemental protection in persons who are expected to have a poor antibody response; and for high-risk persons in whom the vaccine is contraindicated.

HR5: Persons aged $\geq$75 yr or 70-74 yr with one or more additional risk factors, including use of certain psychoactive and cardiac medications (e.g., benzodiazepines, antihypertensives); use of four or more prescription medications; impaired cognition, strength, balance, or gait. Intensive individualized, home-based multifactorial fall prevention intervention is recommended in settings where adequate resources are available to deliver such services.

HR6: Clinicians should consider fasting lipid panel screening on a case-by-case basis for persons aged 65 to 75 yr, especially in those with additional risk factors (e.g., smoking, diabetes, or hypertension).

HR7: Persons with a family or personal history of skin cancer; a large number of moles; atypical moles; poor tanning ability; or light skin, hair, and eye color.

HR8: Blood product recipients (including hemodialysis patients), persons with frequent occupational exposure to blood or blood products, men who have sex with men, injection drug users and their sex partners, persons with multiple recent sex partners, persons with other STDs (including HIV), travelers to countries with endemic hepatitis B.

HR9: Persons who exchange sex for money or drugs and their sex partners, persons with other STDs (including HIV), and sexual contacts of persons with active syphilis. Clinicians should also consider local epidemiology.

HR10: Persons who continue to inject drugs.

HR11: Healthy adults without a history of chickenpox or previous immunization. Consider serologic testing for presumed susceptible adults.

HR12: Consider ultrasound of abdominal aorta to screen for abdominal aortic aneurysm in all men aged 65 to 75 yr who have ever smoked.

TABLE 5-5 Pregnant Women*

Interventions considered and recommended for the Periodic Health Examination

INTERVENTIONS FOR THE GENERAL POPULATION	
Screening	Offer amniocentesis (15-18 wk)[1] (age ≥35 yr)
First visit	Offer multiple marker testing[1] (15-18 wk)
Blood pressure	Offer serum α-fetoprotein[1] (16-18 wk)
Hemoglobin/hematocrit	***Counseling***
Hepatitis B surface antigen (HBsAg)	Tobacco cessation; effects of passive smoking
RPR/VDRL	Alcohol/other drug use
Chlamydia screen (<25 yr)	Nutrition, including adequate calcium intake
Rubella serology or vaccination history	Encourage breastfeeding
D(Rh) typing, antibody screen	Lap/shoulder belts
Offer CVS (<13 wk)[1] or amniocentesis (15-18 wk)[1] (age ≥35 yr)	Infant safety car seats
Offer hemoglobinopathy screening	STD prevention: avoid high-risk sexual behavior†; use condoms†
Assess for problem or risk drinking	***Chemoprophylaxis***
Offer HIV screening[2]	Multivitamin with folic acid[3]
Follow-up visits	
Blood pressure	
Urine culture (12-16 wk)	

INTERVENTIONS FOR HIGH-RISK POPULATIONS	
Population	***Potential Interventions (see detailed high-risk definitions)***
High-risk sexual behavior	Screen for chlamydia (first visit) (HR1), gonorrhea (first visit) (HR2), HIV (first visit) (HR3); HBsAg (third trimester) (HR4); RPR/VDRL (third trimester) (HR5)
Blood transfusion between 1978 and 1985	HIV screen (first visit) (HR3)
Injection drug use	HIV screen (HR3); HBsAg (third trimester) (HR4); advice to reduce infection risk (HR6)
Unsensitized D-negative women	D(Rh) antibody testing (24-28 wk) (HR7)
Risk factors for Down syndrome	Offer CVS (first trimester), amniocentesis (15-18 wk)[1] (HR8)
Prior pregnancy with neural tube defect	Offer amniocentesis (15-18 wk),[1] folic acid 4.0 mg[3] (HR9)

CVS, Chorionic villus sampling; *HR,* high risk; *RPR,* rapid plasma reagin; *VDRL,* Venereal Disease Research Laboratory.
[1]Women with access to counseling and follow-up services, reliable standardized laboratories, skilled high-resolution ultrasound and, for those receiving serum marker testing, amniocentesis capabilities. [2]Universal screening is recommended. [3]Beginning at least 1 mo before conception and continuing through the first trimester.
*See Tables 5-2 and 5-3 for other preventive services recommended for women of this age group.
†The ability of clinician counseling to influence this behavior is unproven.

HR1: Women with history of STD or new or multiple sex partners. Clinicians should also consider local epidemiology. Chlamydia screen should be repeated in third trimester if at continued risk.

HR2: Women younger than 25 yr with two or more sex partners in the last year or whose sex partner has multiple sexual contacts, women who exchange sex for money or drugs, and women with a history of repeated episodes of gonorrhea. Clinicians should also consider local epidemiology. Gonorrhea screen should be repeated in the third trimester if at continued risk.

HR3: Universal screening for HIV infection is recommended for all pregnant women. It is especially important in women with the following individual risk factors: past or present injection drug use; history of exchanging sex for money or drugs; injection drug–using, bisexual, or HIV-positive sex partner currently or in the past; recipients of a blood transfusion between 1978 and 1985; persons seeking treatment for STDs.

HR4: Women who are initially HBsAg negative who are at high risk because of injection drug use, who have suspected exposure to hepatitis B during pregnancy, and who have had multiple sex partners.

HR5: Women who exchange sex for money or drugs, women with other STDs (including HIV), and sexual contacts of persons with active syphilis. Clinicians should also consider local epidemiology.

HR6: Women who continue to inject drugs.

HR7: Unsensitized D-negative women.

HR8: Prior pregnancy affected by Down syndrome, advanced maternal age (≥35 yr), known carriage of chromosome rearrangement.

HR9: Women with previous pregnancy affected by neural tube defect.

Childhood and Adolescent Immunizations

TABLE 5-6 Recommended Immunization Schedule for Persons Aged 0-6 Years—United States
(For those who fall behind or start late, see the catch-up schedule)

Vaccine ▼ Age ▶	Birth	1 Month	2 Months	4 Months	6 Months	12 Months	15 Months	18 Months	19-23 Months	2-3 Years	4-6 Years
Hepatitis B[1]	HepB	HepB		*See footnote 1*	HepB						
Rotavirus[2]			RV	RV	RV[2]						
Diphtheria, tetanus, pertussis[3]			DTaP	DTaP	DTaP	*See footnote 3*	DTaP				DTaP
Haemophilus influenzae type b[4]			Hib	Hib	Hib[4]	Hib					
Pneumococcal[5]			PCV	PCV	PCV	PCV				PPSV	
Inactivated poliovirus			IPV	IPV	IPV						IPV
Influenza[6]					Influenza (yearly)						
Measles, mumps, rubella[7]						MMR		*See footnote 7*			MMR
Varicella[8]						Varicella		*See footnote 8*			Varicella
Hepatitis A[9]						HepA (2 doses)				HepA Series	
Meningococcal[10]										MCV	

Range of recommended ages

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed vaccines for children aged 0-6 years. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the relevant Advisory Committee on Immunization Practices statement for detailed recommendations, including high-risk conditions: http://www.cdc.gov/vaccines/pubs/acip-list.htm. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at http://www.vaers.hhs.gov or by telephone, 800-822-7967.

1. **Hepatitis B vaccine (HepB).** *(Minimum age: birth)*
   At birth:
   - Administer monovalent HepB to all newborns before hospital discharge.
   - If mother is hepatitis B surface antigen (HBsAg)-positive, administer HepB and 0.5 ml of hepatitis B immune globulin (HBIG) within 12 hours of birth.
   - If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine mother's HBsAg status as soon as possible and, if HBsAg-positive, administer HBIG (no later than age 1 week).

   After the birth dose:
   - The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1 or 2 months. Monovalent HepB vaccine should be used for doses administered before age 6 weeks. The final dose should be administered no earlier than age 24 weeks.
   - Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg (anti-HBs) after completion of at least 3 doses of the HepB series, at age 9 through 18 months (generally at the next well-child visit).

   4-month dose:
   - Administration of 4 doses of HepB to infants is permissible when combination vaccines containing HepB are administered after the birth dose. The fourth dose should be administered no earlier than age 24 weeks.
2. **Rotavirus vaccine (RV).** *(Minimum age: 6 weeks)*
   - Administer the first dose at age 6 through 14 weeks *(maximum age: 14 weeks 6 days).* Vaccination should not be initiated for infants aged 15 weeks or older (i.e., 15 weeks, 0 days or older).
   - Administer the final dose in the series by age 8 months 0 days.
   - If Rotarix® is administered at ages 2 and 4 months, a dose at 6 months is not indicated.
3. **Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).** *(Minimum age: 6 weeks)*
   - The fourth dose may be administered as early as age 12 months, provided at least 6 months have elapsed since the third dose.
   - Administer the final dose in the series at age 4 through 6 years.
4. **Haemophilus influenzae type b conjugate vaccine (Hib).** *(Minimum age: 6 weeks)*
   - If PRP-OMP (PedvaxHIB® or Comvax® [HepB-Hib]) is administered at ages 2 and 4 months, a dose at age 6 months is not indicated.
   - TriHiBit® (DTaP/Hib) should not be used for doses at ages 2, 4, or 6 months but can be used as the final dose in children aged 12 months or older.
5. **Pneumococcal vaccine.** *(Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPSV])*
   - PCV is recommended for all children aged younger than 5 years. Administer 1 dose of PCV to all healthy children aged 24 through 59 months who are not completely vaccinated for their age.

   A 13-valent pneumococcal conjugate vaccine (PCV13; Prevnar 13) has replaced PCV7. A single supplemental dose of PCV13 is recommended for healthy children 14 through 59 mo of age who have been completely vaccinated with PCV7. An interval of at least 8 wk is recommended between the final dose of PCV7 and the supplemental dose of PCV13. A supplemental dose is also recommended for children 14 through 71 mo of age who are at high risk of pneumococcal disease (e.g., those with chronic heart and lung disease, diabetes mellitus, sickle cell anemia, asplenia, HIV, cochlear implant, CSF leak or other immunocompromising conditions) and have been completely immunized with PCV7.
6. **Influenza vaccine.** *(Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 2 years for live, attenuated influenza vaccine [LAIV])*
   - Administer annually to children aged 6 months through 18 years
   - For healthy nonpregnant persons (i.e., those who do not have underlying medical conditions that predispose them to influenza complications) aged 2 through 49 years, either LAIV or TIV may be used.
   - Children receiving TIV should receive 0.25 ml if aged 6 through 35 months or 0.5 ml if aged 3 years or older.
   - Administer 2 doses (separated by at least 4 weeks) to children aged younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time during the previous influenza season but only received 1 dose.
7. **Measles, mumps, and rubella vaccine (MMR).** *(Minimum age: 12 months)*
   - Administer the second dose at age 4-6 years. However, the second dose may be administered before age 4, provided at least 28 days have elapsed since the first dose.
8. **Varicella vaccine.** *(Minimum age: 12 months)*
   - Administer the second dose at age 4 through 6 years. However, the second dose may be administered before age 4, provided at least 3 months have elapsed since the first dose.
   - For children aged 12 months through 12 years the minimum interval between doses is 3 months. However, if the second dose was administered at least 28 days after the first dose, it can be accepted as valid.
9. **Hepatitis A vaccine (HepA).** *(Minimum age: 12 months)*
   - Administer to all children aged 1 year (i.e., aged 12 through 23 months). Administer 2 doses at least 6 months apart.
   - Children not fully vaccinated by age 2 years can be vaccinated at subsequent visits.
   - HepA also is recommended for children older than 1 year who live in areas where vaccination programs target older children or who are at increased risk of infection. See *MMWR* 2006;55(No. RR-7).
10. **Meningococcal vaccine.** *(Minimum age: 2 years for meningococcal conjugate vaccine [MCV] and for meningococcal polysaccharide vaccine [MPSV])*
    - Administer MCV to children aged 2 through 10 years with terminal complement component deficiency, anatomic or functional asplenia, and certain other high-risk groups. See *MMWR* 2005;54(No. RR-7).
    - Persons who received MPSV 3 or more years previously and who remain at increased risk for meningococcal disease should be revaccinated with MCV.

Note: The National Childhood Vaccine Injury Act requires that health care providers provide dparents or patients with copies of vaccine information statements before administering each dose of the vaccines listed in the schedules.

The recommended immunization schedules for persons aged 0 to 18 yr are approved by the Advisory Committee on Immunization Practices (http://www.cdc.gov/vaccines/recs/acip), the American Academy of Pediatrics (http://www.aap.org), and the American Academy of Family Physicians (http://www.aafp.org).

TABLE 5-7 Recommended Immunization Schedule for Persons Aged 7-18 Years—United States (For those who fall behind or start late, see the schedule below and the catch-up schedule)

This schedule indicates the recommended ages for routine administration of currently licensed vaccines for children aged 7-18 years. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations, including high-risk conditions: http://www.cdc.gov/vaccines/pubs/acip-list.htm. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at http://www.vaers.hhs.gov or by telephone, 800-822-7967.

1. **Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).** *(Minimum age: 10 years for BOOSTRIX® and 11 years for ADACEL®)*
   - Administer at age 11 or 12 years for those who have completed the recommended childhood DTP/DTaP vaccination series and have not received a tetanus and diphtheria toxoid (Td) booster dose.
   - Persons aged 13 to 18 years who have not received Tdap should receive a dose.
   - A 5-year interval from the last Td dose is encouraged when Tdap is used as a booster dose; however, a shorter interval may be used if pertussis immunity is needed.
2. **Human papillomavirus vaccine (HPV).** *(Minimum age: 9 years)*
   - Two HPV vaccines are licensed: A quadrivalent vaccine (HPV4) for the prevention of cervical, vaginal, and vulvar cancer (in females) and genital warts (in females and males) and a bivalent vaccine (HPV2) for the prevention of cervical cancers in females.
   - HPV4 is recommended for the prevention of cervical, vaginal, and vulvar precancers and cancers and genital warts in females and genital warts in males.
   - Administer the first dose to females at age 11 or 12 years.
   - Administer the second dose 2 months after the first dose and the third dose 6 months after the first dose (at least 24 weeks after the first dose).
   - Administer the series to females at age 13 to 18 years if not previously vaccinated.
   - HPV4 may be administered in a 3-dose series to males aged 9 through 18 years to reduce the likelihood of acquiring genital warts.
3. **Meningococcal conjugate vaccine (MCV).**
   - Administer at age 11 or 12 years, or at age 13 to 18 years if not previously vaccinated.
   - Administer to previously unvaccinated college freshmen living in a dormitory.
   - Administer MCV4 to children aged 2 through 10 years with complement component deficiency, anatomic or functional asplenia, or certain other conditions placing them at high risk.
   - Administer to children previously vaccinated with MCV4 or MPSV4 who remain at increased risk after 3 years (if first dose administered at age 7 years or older). Persons whose only risk factor is living in on-campus housing are not recommended to receive an additional dose. See *MMWR* 2009;58:1042-1043.
4. **Influenza vaccine.**
   - Administer annually to children aged 6 months to 18 years.
   - For healthy, nonpregnant persons (i.e., those who do not have underlying medical conditions that predispose them to influenza complications) aged 2 to 49 years, either LAIV or TIV may be used.
   - Administer 2 doses (separated by at least 4 weeks) to children aged younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time during the previous influenza season but only received 1 dose.
5. **Pneumococcal polysaccharide vaccine (PPSV).**
   - Administer to children with certain underlying medical conditions (see *MMWR* 1997;46[No. RR-8]), including a cochlear implant. A single revaccination should be administered to children with functional or anatomic asplenia or other immunocompromising condition after 5 years. (See previous page, pneumococcal vaccine.)
6. **Hepatitis A vaccine (HepA).**
   - Administer 2 doses at least 6 months apart.
   - HepA is recommended for children older than 23 months who live in areas where vaccination programs target older children, who are at increased risk for infection, or for whom immunity against hepatitis A is desired.
7. **Hepatitis B vaccine (HepB).**
   - Administer the 3-dose series to those not previously vaccinated.
   - A 2-dose series (separated by at least 4 months) of adult formulation Recombivax HB® is licensed for children aged 11 to 15 years.
8. **Inactivated poliovirus vaccine (IPV).**
   - For children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if the third dose was administered at age 4 years or older.
   - If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.
9. **Measles, mumps, and rubella vaccine (MMR).**
   - If not previously vaccinated, administer 2 doses or the second dose for those who have received only 1 dose, with at least 28 days between doses.
10. **Varicella vaccine.**
    - For persons aged 7 to 18 years without evidence of immunity (see *MMWR* 2007;56[No. RR-4]), administer 2 doses if not previously vaccinated or the second dose if they have received only 1 dose.
    - For persons aged 7 to 12 years, the minimum interval between doses is 3 months. However, if the second dose was administered at least 28 days after the first dose, it can be accepted as valid.
    - For persons aged 13 years and older, the minimum interval between doses is 28 days.

The recommended immunization schedules for persons aged 0 to 18 yr are approved by the Advisory Committee on Immunization Practices (http://www.cdc.gov.vaccines.recs.acip), the American Academy of Pediatrics (http://www.aap.org), and the American Academy of Family Physicians (http://www.aafp.org).

TABLE 5-8 Catch-Up Immunization Schedule for Persons Aged 4 Months to 18 Years Who Start Late or Who Are More than 1 Month Behind—United States

This table provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

CATCH-UP SCHEDULE FOR PERSONS AGED 4 MONTHS TO 6 YEARS					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
Hepatitis B[1]	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Rotavirus[2]	6 weeks	4 weeks	4 weeks[2]		
Diphtheria,tetanus, pertussis[3]	6 weeks	4 weeks	4 weeks	6 months	6 months[3]
Haemophilus influenzae type b[4]	6 weeks	4 weeks if first dose administered at younger than 12 months of age 8 weeks (as final dose) if first dose administered at age 12-14 months No further doses needed if first dose administered at age 15 months or older	4 weeks[4] if current age is younger than 12 months 8 weeks (as final dose)[4] if current age is 12 months or older and second dose administered at younger than 15 months of age No further doses needed if previous dose administered at age 15 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 3 doses before age 12 months	
Pneumococcal[5]	6 weeks	4 weeks if first dose administered at younger than 12 months of age 8 weeks (as final dose for healthy children) if first dose administered at age 12 months or older or current age 24 to 59 months No further doses needed for healthy children if first dose administered at age 24 months or older	4 weeks if current age is younger than 12 months 8 weeks (as final dose for healthy children) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months to 59 months who received 3 doses before age 12 months or for high-risk children who received 3 doses at any age	
Inactivated poliovirus[6]	6 weeks	4 weeks	4 weeks	4 weeks[6]	
Measles, mumps, rubella[7]	12 months	4 weeks			
Varicella[8]	12 months	3 months			
Hepatitis A[9]	12 months	6 months			
CATCH-UP SCHEDULE FOR PERSONS AGED 7 TO 18 YEARS					
Tetanus, diphtheria/ tetanus, diphtheria, pertussis[10]	7 years[10]	4 weeks	4 weeks if first dose administered at younger than 12 months of age 6 months if first dose administered at age 12 months or older	6 months if first dose administered at younger than 12 months of age	
Human papillomavirus[11]	9 years	Routine dosing intervals are recommended[11]			
Hepatitis A[9]	12 months	6 months			
Hepatitis B[1]	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Inactivated poliovirus[6]	6 weeks	4 weeks	4 weeks	6 months	
Measles, mumps, rubella[7]	12 months	4 weeks			
Varicella[8]	12 months	3 months if the person is younger than age 13 years of age 4 weeks if the person is aged 13 years or older			

1. **Hepatitis B vaccine (HepB).**
   - Administer the 3-dose series to those not previously vaccinated.
   - A 2-dose series (separated by at least 4 mo) of adult formulation Recombivax HB is licensed for children aged 11 to 15 yr.
2. **Rotavirus vaccine (RV).**
   - The maximum age for the first dose is 14 wk 6 days. Vaccination should not be initiated for infants aged 15 wk or older (i.e., 15 wk 0 days or older).
   - Administer the final dose in the series by age 8 mo 0 days.
   - If Rotarix was administered for the first and second doses, a third dose is not indicated.
3. **Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).**
   - The fifth dose is not necessary if the fourth dose was administered at age 4 yr or older.
4. ***Haemophilus influenzae* type b conjugate vaccine (Hib).**
   - Hib vaccine is not generally recommended for persons aged 5 yr or older. No efficacy data are available on which to base a recommendation concerning use of Hib vaccine for older children and adults. However, studies suggest good immunogenicity in persons who have sickle cell disease, leukemia, or HIV infection, or who have had a splenectomy; administering 1 dose of Hib vaccine to these persons is not contraindicated.
   - If the first 2 doses were PRP-OMP (PedvaxHIB or Comvax), and administered at age 11 mo or younger, the third (and final) dose should be administered at age 12 to 15 mo and at least 8 wk after the second dose.
   - If the first dose was administered at age 7 to 11 mo, administer 2 doses separated by 4 wk and a final dose at age 12 to 15 mo.
5. **Pneumococcal vaccine.**
   - Administer 1 dose of pneumococcal conjugate vaccine (PCV) to all healthy children aged 24 to 59 mo who have not received at least 1 dose of PCV on or after age 12 mo.
   - For children aged 24 to 59 mo with underlying medical conditions, administer 1 dose of PCV if 3 doses were received previously or administer 2 doses of PCV at least 8 wk apart if fewer than 3 doses were received previously.
   - Administer pneumococcal polysaccharide vaccine (PPSV) to children aged 2 yr or older with certain underlying medical conditions (see *MMWR* 49(RR-9), 2000), including a cochlear implant, at least 8 wk after the last dose of PCV. (See Table 5-6, pneumococcal vaccine.)
6. **Inactivated poliovirus vaccine (IPV).**
   - The final dose in the series should be administered on or after the fourth birthday and at least 6 months following the previous dose.
   - A fourth dose is not necessary if the third dose was administered at age 4 or older and at least 6 months following the previous dose.
   - In the first 6 months of life, minimum age and minimum intervals are only recommended if the person is at risk for imminent exposure to circulating poliovirus (i.e., travel to a polio-endemic region or during an outbreak).
7. **Measles, mumps, and rubella vaccine (MMR).**
   - Administer the second dose at age 4 to 6 yr. However, the second dose may be administered before age 4, provided at least 28 days have elapsed since the first dose.
   - If not previously vaccinated, administer 2 doses with at least 28 days between doses.
8. **Varicella vaccine.**
   - Administer the second dose at age 4 to 6 yr. However, the second dose may be administered before age 4, provided at least 3 mo have elapsed since the first dose.
   - For persons aged 12 mo to 12 yr, the minimum interval between doses is 3 mo. However, if the second dose was administered at least 28 days after the first dose, it can be accepted as valid.
   - For persons aged 13 yr and older, the minimum interval between doses is 28 days.
9. **Hepatitis A vaccine (HepA).**
   - HepA is recommended for children older than 1 yr who live in areas where vaccination programs target older children or who are at increased risk of infection. See *MMWR* 55(RR-7), 2006.
10. **Tetanus and diphtheria toxoids vaccine (Td) and tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).**
    - Doses of DTaP are counted as part of the Td/Tdap series.
    - dap should be substituted for a single dose of Td in the catch-up series or as a booster for children aged 10 to 18 yr; use Td for other doses.
11. **Human papillomavirus vaccine (HPV).**
    - Administer the series to females at age 13 to 18 yr if not previously vaccinated and to males aged 9 to 26.
    - Use recommended routine dosing intervals for series catch-up (i.e., the second and third doses should be administered at 2 and 6 mo after the first dose). However, the minimum interval between the first and second doses is 4 wk. The minimum interval between the second and third doses is 12 wk, and the third dose should be given at least 24 wk after the first dose.

Information about reporting reactions after immunization is available online at http://www.vaers.hhs.gov or by telephone, 800-822-7967. Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for immunization, is available from the National Center for Immunization and Respiratory Diseases at http://www.cdc.gov/vaccines or by telephone at 800-CDC-INFO (800-232-4636).

QUADRIVALENT HUMAN PAPILLOMAVIRUS (HPV) VACCINE*

SUMMARY OF RATIONALE FOR QUADRIVALENT HPV VACCINE RECOMMENDATIONS*

The availability of a quadrivalent HPV vaccine offers an opportunity to decrease the burden of HPV infection and its sequelae, including cervical cancer precursors, cervical cancer, other anogenital cancers, and genital warts, in the United States. Quadrivalent HPV vaccine is licensed for use among females and males aged 9 to 26 years. HPV4 may also be administered in a 3-dose series to males aged 9 through 18 years to reduce their likelihood of acquiring genital warts. In this age group, clinical trials indicate that the vaccine is safe and immunogenic. Trials among females aged 16 to 26 years indicated the vaccine (Gardasil) to be effective against HPV types 6-, 11-, 16-, and 18-related cervical, vaginal, and vulvar cancer precursors and dysplastic lesions and genital warts. HPV 16 and 18 cause approximately 70% of cervical cancers; HPV 6 and 11 cause approximately 90% of genital warts. A new HPV vaccine (Cervarix) has been approved. Cervarix is bivalent and targets two oncogenic types, HPV 16 and 18. Because HPV is sexually transmitted and often acquired soon after onset of sexual activity, vaccination should ideally occur before first sexual activity. The recommended age for vaccination is 11 to 12 years; vaccine can be administered to girls as young as age 9 years. At the beginning of a vaccination program, females older than 12 years will exist who did not have the opportunity to receive vaccine at age 11 to 12 years. Catch-up vaccination is recommended for females aged 13 to 26 years who have not yet been vaccinated.

The recommendation for routine vaccination of girls aged 11 to 12 years is based on several considerations, including studies suggesting that quadrivalent HPV vaccine among adolescents will be safe and effective, high antibody titers achieved after vaccination at age 11 to 12 years, data on HPV epidemiology and age of sexual debut in the United States, and the high probability of HPV acquisition within several years of first sexual activity. Ideally, HPV vaccine should be administered before first sexual activity, and duration of protection should extend for many years, providing protection when exposure through sexual activity might occur. The vaccine has been demonstrated to provide protection for at least 5 years without evidence of waning. Long-term follow-up studies are under way to determine duration of protection. The recommendation also considered cost-effectiveness evaluations and the established young adolescent health care visit at age 11 to 12 years recommended by several professional organizations, when other vaccines are also recommended.

Although routine vaccination is recommended at age 11 to 12 years, the majority of females aged 13 to 26 years also can benefit from vaccination. Females not yet sexually active can be expected to receive the full benefit of vaccination. Although sexually active females in this age group might have been infected with one or more vaccine HPV types, type-specific prevalence studies in the United States suggest that a small percentage of sexually active females have been infected with all four of the HPV vaccine types. These data, available from North American females aged 16 to 24 years who participated in the quadrivalent vaccine trials, are from women who were more likely to have ever had sex than similarly aged females in the general U.S. population. Among those sexually active females, the median number of lifetime sex partners (two) was similar in trial participants and females in the general U.S. population. The vaccine does not appear to protect against persistent infection, cervical cancer precursor lesions, or genital warts caused by an HPV type that females are infected with at the time of vaccination. However, females already infected with one or more vaccine HPV types before vaccination would be protected against disease caused by the other vaccine HPV types. Therefore although overall vaccine effectiveness would be lower when administered to a population of females who are sexually active and would decrease with older age and likelihood of HPV exposure with increasing number of sex partners, the majority of females in this age group will derive at least partial benefit from vaccination.

*From CDC: Quadrivalent human papillomavirus vaccine: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 56(RR-2):16-18, 2007.

RECOMMENDATIONS FOR USE OF HPV VACCINE

RECOMMENDATIONS FOR ROUTINE USE AND CATCH-UP

Routine Vaccination of Females Aged 11 to 12 Years

The Advisory Committee on Immunization Practices (ACIP) recommends routine vaccination of females aged 11 to 12 years with 3 doses of quadrivalent HPV vaccine. The vaccination series can be started as young as age 9 years.

Catch-Up Vaccination of Females Aged 13-26 Years

Vaccination also is recommended for females aged 13 to 26 years who have not been previously vaccinated or who have not completed the full series. Ideally, vaccine should be administered before potential exposure to HPV through sexual contact; however, females who might have already been exposed to HPV should be vaccinated. Sexually active females who have not been infected with any of the HPV vaccine types would receive full benefit from vaccination. Vaccination would provide less benefit to females if they have already been infected with one or more of the four vaccine HPV types. However, clinicians cannot assess the extent to which sexually active persons would benefit from vaccination, and the risk for HPV infection might continue as long as persons are sexually active. Pap testing and screening for HPV DNA or HPV antibody are not needed before vaccination at any age.

Dosage and Administration

The vaccine should be shaken well before administration. The dose of quadrivalent HPV vaccine is 0.5 ml, administered intramuscularly (IM), preferably in the deltoid muscle.

Recommended Schedule

Quadrivalent HPV vaccine is administered in a 3-dose schedule. The second and third doses should be administered 2 and 6 months after the first dose.

Minimum Dosing Intervals and Management of Persons Who Were Incorrectly Vaccinated

The minimum interval between the first and second doses of vaccine is 4 weeks. The minimum recommended interval between the second and third doses of vaccine is 12 weeks. Inadequate doses of quadrivalent HPV vaccine or vaccine doses received after a shorter-than-recommended dosing interval should be readministered.

Interrupted Vaccine Schedules

If the quadrivalent HPV vaccine schedule is interrupted, the vaccine series does not need to be restarted. If the series is interrupted after the first dose, the second dose should be administered as soon as possible and separated from the third dose by an interval of at least 12 weeks. If only the third dose is delayed, it should be administered as soon as possible.

Simultaneous Administration with Other Vaccines

Although no data exist on administration of quadrivalent HPV vaccine with vaccines other than hepatitis B vaccine, quadrivalent HPV vaccine is not a live vaccine and has no components that adversely affect safety or efficacy of other vaccinations. Quadrivalent HPV vaccine can be administered at the same visit as other age-appropriate vaccines, such as the diphtheria, tetanus, pertussis (DTP), and quadrivalent meningococcal conjugate (MCV4) vaccines. Administering all indicated vaccines together at a single visit increases the likelihood that adolescents and young adults will receive each of the vaccines on schedule. Each vaccine should be administered by a separate syringe at a different anatomic site.

Cervical Cancer Screening among Vaccinated Females

Cervical cancer screening recommendations have not changed for females who receive HPV vaccine. HPV types in the vaccine are responsible for approximately 70% of cervical cancers; females who are vaccinated could subsequently be infected with a carcinogenic HPV type for which the quadrivalent vaccine does not provide protection. Furthermore, those who were sexually active before vaccination could have been infected with a vaccine-type HPV before vaccination. Health care providers administering quadrivalent HPV vaccine should educate women about the importance of cervical cancer screening.

Vaccination of Males
Quadrivalent HPV vaccine is now licensed for use in males ages 9 to 26 for the prevention of genital warts.

GROUPS FOR WHICH VACCINE IS NOT LICENSED
Vaccination of Females Aged <9 Years and >26 Years
Quadrivalent HPV vaccine is not licensed for use in girls younger than 9 years or women older than 26 years. Studies are ongoing among women older than 26 years. No studies are underway among girls younger than 9 years.

SPECIAL SITUATIONS AMONG FEMALES AGED 9 TO 26 YEARS
Equivocal or Abnormal Pap Test or Known HPV Infection
Females who have an equivocal or abnormal Pap test could be infected with any of approximately 40 high-risk or low-risk genital HPV types. Such females are unlikely to be infected with all four HPV vaccine types, and they might not be infected with any HPV vaccine type. Vaccination would provide protection against infection with HPV vaccine types not already acquired. With increasing severity of Pap test findings, the likelihood of infection with HPV 16 or 18 increases and the benefit of vaccination would decrease. Women should be advised that results from clinical trials do not indicate the vaccine will have any therapeutic effect on existing HPV infection or cervical lesions.

Females who have a positive HC2 high-risk test result conducted in conjunction with a Pap test could have infection with any of 13 high-risk types. This assay does not identify specific HPV types, and testing for specific HPV types is not conducted routinely in clinical practice. Women with a positive HC2 high-risk test result might not have been infected with any of the four HPV vaccine types. Vaccination would provide protection against infection with HPV vaccine types not already acquired. However, women should be advised that results from clinical trials do not indicate the vaccine will have any therapeutic effect on existing HPV infection or cervical lesions.

Genital Warts
A history of genital warts or clinically evident genital warts indicates infection with HPV, most often types 6 or 11. However, these females might not have infection with both HPV 6 and 11 or infection with HPV 16 or 18. Vaccination would provide protection against infection with HPV vaccine types not already acquired. However, females should be advised that results from clinical trials do not indicate the vaccine will have any therapeutic effect on existing HPV infection or genital warts.

Lactating Women
Lactating women can receive the HPV vaccine.

Immunocompromised Persons
Because quadrivalent HPV vaccine is a noninfectious vaccine, it can be administered to females who are immunosuppressed as a result of disease or medications. However, the immune response and vaccine efficacy might be less than that in persons who are immunocompetent.

Vaccination during Pregnancy
Quadrivalent HPV vaccine is not recommended for use in pregnancy. The vaccine has not been causally associated with adverse outcomes of pregnancy or adverse events in the developing fetus. However, data on vaccination during pregnancy are limited. Until additional information is available, initiation of the vaccine series should be delayed until after completion of the pregnancy. If a woman is found to be pregnant after initiating the vaccination series, the remainder of the 3-dose regimen should be delayed until after completion of the pregnancy. If a vaccine dose has been administered during pregnancy, no intervention is needed. A vaccine-in-pregnancy registry has been established; patients and health care providers should report any exposure to quadrivalent HPV vaccine during pregnancy by calling 800-986-8999.

PRECAUTIONS AND CONTRAINDICATIONS
Acute Illnesses
Quadrivalent HPV vaccine can be administered to persons with minor acute illnesses (e.g., diarrhea or mild upper respiratory tract infections with or without fever). Vaccination of persons with moderate or severe acute illnesses should be deferred until after the patient improves.

Hypersensitivity or Allergy to Vaccine Components
Quadrivalent HPV vaccine is contraindicated for persons with a history of immediate hypersensitivity to yeast or to any vaccine component. Data from passive surveillance in the Vaccine Adverse Event Reporting System (VAERS) indicate that recombinant yeast-derived vaccines pose a minimal risk for anaphylactic reactions in persons with a history of allergic reactions to *Saccharomyces cerevisiae* (baker's yeast).

Preventing Syncope after Vaccination
Syncope (i.e., vasovagal or vasodepressor reaction) can occur after vaccination, most commonly among adolescents and young adults. Among reports to VAERS for any vaccine that was coded as triggering syncope from 1990 to 2004, 35% of these episodes were reported among persons aged 10 to 18 years. Through January 2007, the second most common report to VAERS after receipt of HPV vaccine was syncope (Centers for Disease Control and Prevention, unpublished data, 2007). Vaccine providers should consider observing patients for 15 minutes after they receive HPV vaccine.

General Recommendations on Immunization

TABLE 5-9 Recommended and Minimum Ages and Intervals between Vaccine Doses of Routinely Recommended Vaccines[a]

Vaccine and Dose Number	Recommended Age for this Dose	Minimum Age for this Dose	Recommended Interval to Next Dose	Minimum Interval to Next Dose
Hepatitis B (HepB)-1[b]	Birth	Birth	1-4 mo	4 wk
HepB-2	1-2 mo	4 wk	2-17 mo	8 wk
HepB-3[c]	6-18 mo	24 wk	—	—
Diphtheria-tetanus-acellular pertussis (DTaP)-1[b]	2 mo	6 wk	2 mo	4 wk
DTaP-2	4 mo	10 wk	2 mo	4 wk
DTaP-3	6 mo	14 wk	6-12 mo[d]	6 mo[d,e]
DTaP-4	15-18 mo	12 mo	3 yr	6 mo[d]
DTaP-5	4-6 yr	4 yr	—	—
Haemophilus influenzae type b (Hib)-1[b,f]	2 mo	6 wk	2 mo	4 wk
Hib-2	4 mo	10 wk	2 mo	4 wk
Hib-3[g]	6 mo	14 wk	6-9 mo[d]	8 wk
Hib-4	12-15 mo	12 mo	—	—
Inactivated poliovirus (IPV)-1[b]	2 mo	6 wk	2 mo	4 wk
IPV-2	4 mo	10 wk	2-14 mo	4 wk
IPV-3	6-18 mo	14 wk	3-5 yr	4 wk
IPV-4	4-6 yr	18 wk	—	—

TABLE 5-9 Recommended and Minimum Ages and Intervals between Vaccine Doses of Routinely Recommended Vaccines—cont'd

From CDC: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-15), 2006.

[a]Combination vaccines are available. Use of licensed combination vaccines is preferred over separate injections of their equivalent component vaccines. (Source: CDC: Combination vaccines for childhood immunization: recommendations of the Advisory Committee on Immunization Practices [ACIP], the American Academy of Pediatrics [AAP], and the American Academy of Family Physicians [AAFP], *MMWR* 48:[RR-5], 1999.) When administering combination vaccines, the minimum age for administration is the oldest age for any of the individual components; the minimum interval between doses is equal to the greatest interval of any of the individual components.

[b]Combination vaccines containing the hepatitis B component are available (HepB-Hib, DTaP-HepB-IPV, and HepA-HepB). These vaccines should not be administered to infants aged $<$6 wk because of the other components (i.e., Hib, DTaP, HepA, and IPV).

[c]HepB-3 should be administered at least 8 wk after HepB-2 and at least 16 wk after HepB-1 and should not be administered before age 24 wk.

[d]Calendar months.

[e]The minimum recommended interval between DTaP-3 and DTaP-4 is 6 mo. However, DTaP-4 need not be repeated if administered at least 4 mo after DTaP-3.

[f]For Hib and PCV, children receiving the first dose of vaccine at age $\geq$7 mo require fewer doses to complete the series. (Source: Centers for Disease Control and Prevention: Recommended childhood and adolescent immunization schedule—United States, 2006, *MMWR* 54[51 & 52]:Q1-Q4, 2005.)

[g]If PRP-OMP (Pedvax-Hib, Merck) was administered at age 2 and 4 mo, a dose at age 6 mo is not required.

[h]Combination measles-mumps-rubella-varicella (MMRV) vaccine can be used for children aged 12 mo to 12 yr.

[i]The minimum interval from VAR-1 to VAR-2 for persons beginning the series at age $\geq$13 yr is 4 wk.

[j]Two doses of influenza vaccine are recommended for children aged $<$9 yr who are receiving the vaccine for the first time. Children aged $<$9 yr who have previously received influenza vaccine and persons aged $\geq$9 yr require only 1 dose per influenza season.

[k]The minimum age for inactivated influenza vaccine varies by vaccine manufacturer. Only Fluzone (Sanofi Pasteur) is approved for children aged 6-35 mo. The minimum age for Fluvirin (Novartis) is 4 yr. For Fluarix and FluLeval (GlaxoSmithKline), the minimum age is 18 yr.

[l]Certain experts recommend a second dose of MPSV 3 yr after the first dose for persons at increased risk for meningococcal disease.

[m]A second dose of meningococcal vaccine is recommended for persons previously vaccinated with MPSV who remain at high risk for meningococcal disease. MCV4 is preferred when revaccinating persons aged 11-55 yr, but a second dose of MPSV is acceptable. (Source: Centers for Disease Control and Prevention: Prevention and control of meningococcal disease: recommendations of the Advisory Committee on Immunization Practices [ACIP], *MMWR* 54:[RR-7], 2005.)

[n]Only 1 dose of Tdap is recommended. Subsequent doses should be administered as Td. If vaccination to prevent tetanus and/or diphtheria disease is required for children aged 7-9 yr, Td should be administered (minimum age for Td is 7 yr). For one brand of Tdap, the minimum age is 11 yr. The preferred interval between Tdap and a previous dose of Td is 5 yr. In persons who have received a primary series of tetanus-toxoid-containing vaccine, for management of a tetanus-prone wound, the minimum interval after a previous dose of any tetanus-containing vaccine is 5 yr.

[o]A second dose of PPV is recommended for persons at highest risk for serious pneumococcal infection and those who are likely to have a rapid decline in pneumococcal antibody concentration. Revaccination 3 yr after the previous dose can be considered for children at highest risk for severe pneumococcal infection who would be aged $<$10 yr at the time of revaccination. (Source: Centers for Disease Control and Prevention: Prevention of pneumococcal disease: recommendations of the Advisory Committee on Immunization Practices [ACIP], *MMWR* 46:[RR-8], 1997.)

[p]HPV is approved for both males and females aged 9-26 yr.

[q]The first dose of RV must be administered at age 6-12 wk. The vaccine series should not be started at age $\geq$13 wk. RV should not be administered to children aged $\geq$33 wk regardless of the number of doses received at age 6-32 wk.

[r]Herpes zoster vaccine is approved as a single dose for persons who are aged $\geq$60 yr with a history of varicella.

TABLE 5-10 Guidelines for Spacing of Live and Inactivated Antigens

Antigen Combination	Recommended Minimum Interval between Doses
Two or more inactivated*	Can be administered simultaneously or at any interval between doses
Inactivated and live	Can be administered simultaneously or at any interval between doses
Two or more live intranasal or injectable†	4-wk minimum interval if not administered simultaneously

From Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-15), 2006.

*Certain experts suggest a 1-mo interval between tetanus toxoid, reduced diphtheria toxoid, and reduced acellular pertussis vaccine and quadrivalent meningococcal conjugate vaccine if they are not administered simultaneously.

†Live oral vaccines (e.g., Ty21a typhoid vaccine and rotavirus vaccine) can be administered simultaneously or at any interval before or after inactivated or live injectable vaccines.

TABLE 5-11 Guidelines for Administering Antibody-Containing Products* and Vaccines

SIMULTANEOUS ADMINISTRATION

Combination	Recommended Minimum Interval between Doses
Antibody-containing products and inactivated antigen	Can be administered simultaneously at different sites or at any time interval between doses.
Antibody-containing products and live antigen	Should not be administered simultaneously.† If simultaneous administration of measles-containing vaccine or varicella vaccine is unavoidable, administer at different sites and revaccinate or test for seroconversion after the recommended interval.

NONSIMULTANEOUS ADMINISTRATION

PRODUCT ADMINISTERED		
First	**Second**	**Recommended Minimum Interval between Doses**
Antibody-containing products	Inactivated antigen	Not applicable
Inactivated antigen	Antibody-containing products	Not applicable
Antibody-containing products	Live antigen	Dose-related†‡§
Live antigen	Antibody-containing products	2 weeks†

From Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-15), 2006.

*Blood products containing substantial amounts of immunoglobulin include intramuscular and intravenous immune globulin, specific hyperimmune globulin (e.g., hepatitis B immune globulin, tetanus immune globulin, varicella zoster immune globulin, and rabies immune globulin), whole blood, packed red cells, plasma, and platelet products.

†Yellow fever, oral Ty21a typhoid vaccine, and live-attenuated influenza vaccine are exceptions to these recommendations. These live-attenuated vaccines can be administered at any time before, after, or simultaneously with an antibody-containing product without substantially decreasing the antibody response.

‡Rotavirus vaccine (RV) should be deferred for 6 wk after receipt of an antibody-containing product if possible. However, if the 6-wk deferral would cause the first dose of RV to be scheduled for age $>$13 wk, a shorter deferral interval should be used to ensure the first dose of RV is administered no later than age 13 wk.

§The duration of interference of antibody-containing products with the immune response to the measles component of measles-containing vaccine, and possibly varicella vaccine, is dose related.

TABLE 5-12 Suggested Intervals between Administration of Antibody-Containing Products for Different Indications and Measles-Containing Vaccine and Varicella-Containing Vaccine*

Product/Indication	Dose, Including mg Immunoglobulin G (IgG)/kg Body Weight*	Recommended Interval before Measles or Varicella-Containing Vaccine Administration (mo)
Respiratory syncytial virus immune globulin (IG) monoclonal antibody (Synagis)†	15 mg/kg intramuscularly (IM)	None
Tetanus IG	250 units (10 mg IgG/kg) IM	3
Hepatitis A IG		
Contact prophylaxis	0.02 ml/kg (3.3 mg IgG/kg) IM	3
International travel	0.06 ml/kg (10 mg IgG/kg) IM	3
Hepatitis B IG	0.06 ml/kg (10 mg IgG/kg) IM	3
Rabies IG	20 international units/kg (22 mg IgG/kg) IM	4
Measles prophylaxis IG		
Standard (i.e., nonimmunocompromised) contact	0.25 ml/kg (40 mg IgG/kg) IM	5
Immunocompromised contact	0.50 ml/kg (80 mg IgG/kg) IM	6
Blood transfusion		
Red blood cells (RBCs), washed	10 ml/kg negligible IgG/kg intravenously (IV)	None
RBCs, adenine-saline added	10 ml/kg (10 mg IgG/kg) IV	3
Packed RBCs (hematocrit 65%)‡	10 ml/kg (60 mg IgG/kg) IV	6
Whole blood (hematocrit 35%-50%)‡	10 ml/kg (80-100 mg IgG/kg) IV	6
Plasma/platelet products	10 ml/kg (160 mg IgG/kg) IV	7
Cytomegalovirus intravenous immune globulin (IGIV)	150 mg/kg maximum	6
IGIV		
Replacement therapy for immune deficiencies§	300-400 mg/kg IV§	8
Immune thrombocytopenic purpura	400 mg/kg IV	8
Postexposure varicella prophylaxis¶	400 mg/kg IV	8
Immune thrombocytopenic purpura	1000 mg/kg IV	10
Kawasaki disease	2 g/kg IV	11

From Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-15), 2006.

*This table is not intended to provide the correct indications and dosages for using antibody-containing products. Unvaccinated persons might not be fully protected against measles during the entire recommended interval, and additional doses of immune globulin or measles vaccine might be indicated after measles exposure. Concentrations of measles antibody in an immune globulin preparation can vary by manufacturer's lot. Rates of antibody clearance after receipt of an immune globulin preparation also may vary. Recommended intervals are extrapolated from an estimated half-life of 30 days for passively acquired antibody and an observed interference with the immune response to measles vaccine for 5 mo after a dose of 80 mg IgG/kg.

†Contains antibody only to respiratory syncytial virus.

‡Assumes a serum IgG concentration of 16 mg/ml.

§Measles and varicella vaccinations are recommended for children with asymptomatic or mildly symptomatic human immunodeficiency virus (HIV) infection but are contraindicated for persons with severe immunosuppression from HIV or any other immunosuppressive disorder.

¶The investigational product VariZIG, similar to licensed VZIG, is a purified human immune globulin preparation made from plasma containing high levels of antivaricella antibodies (immunoglobulin class G [IgG]). When indicated, health care providers should make every effort to obtain and administer VariZIG. In situations in which administration of VariZIG does not appear possible within 96 hours of exposure, administration of immune globulin intravenous (IGIV) should be considered as an alternative. IGIV also should be administered within 96 hours of exposure. Although licensed IGIV preparations are known to contain antivaricella antibody titers, the titer of any specific lot of IGIV that might be available is uncertain because IGIV is not routinely tested for antivaricella antibodies. The recommended IGIV dose for postexposure prophylaxis of varicella is 400 mg/kg administered once. For pregnant women who cannot receive VariZIG within 96 hours of exposure, clinicians can choose either to administer IGIV or closely monitor the women for signs and symptoms of varicella and institute treatment with acyclovir if illness occurs. (Source: Centers for Disease Control and Prevention: A new product for postexposure prophylaxis available under an investigational new drug application expanded access protocol, *MMWR* 55 [RR-8]:209-210, 2006.)

TABLE 5-13 Contraindications to and Precautions for Commonly Used Vaccines[a]

Vaccine	True Contraindications and Precautions[a]	Untrue (Vaccines Can Be Administered)
General for all routine vaccines, including diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP); pediatric diphtheria-tetanus toxoid (DT); adult tetanus-diphtheria toxoid (Td); tetanus-reduced-diphtheria toxoid and acellular pertussis vaccine (Tdap), inactivated poliovirus vaccine (IPV); measles, mumps, and rubella vaccine (MMR); *Haemophilus influenzae* type b vaccine (Hib); hepatitis A vaccine; hepatitis B vaccine; varicella vaccine; Rotavirus vaccine; pneumococcal conjugate vaccine (PCV); inactivated influenza vaccine (TIV); live-attenuated influenza vaccine (LAIV); pneumococcal polysaccharide vaccine (PPV); meningococcal conjugate vaccine (MCV4); meningococcal polysaccharide vaccine (MPSV); human papillomavirus vaccine (HPV); and herpes zoster vaccine (HZ)	***Contraindication*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component ***Precaution*** Moderate or severe acute illness with or without fever	Mild acute illness with or without fever Mild-to-moderate local reaction (e.g., swelling, redness, and soreness), low-grade or moderate fever Lack of previous physical examination in well-appearing person after current antimicrobial therapy[b] Previous convalescent preterm birth (hepatitis B vaccine is an exception in certain circumstances)[c] phase of illness dose Recent exposure to an infectious disease History of penicillin allergy, other nonvaccine allergies, relatives with allergies, receiving allergen extract immunotherapy Breastfeeding
DTaP	***Contraindications*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component Encephalopathy (e.g., coma, decreased level of consciousness, prolonged seizures) not attributable to another identifiable cause within 7 days of administration of previous dose of DTP or DTaP Progressive neurologic disorder, including infantile spasms, uncontrolled epilepsy, progressive encephalopathy: defer DTaP until neurologic status clarified and stabilized ***Precautions*** Temperature of ≥105° F (≥40.5° C) ≤48 hours after vaccination with a previous dose of DTP or DTaP Collapse or shocklike state (i.e., hypotonic hyporesponsive episode) ≤48 hours after receiving a previous dose of DTP/DTaP Seizure ≤3 days after receiving a previous dose of DTP/DTaP[d] Persistent, inconsolable crying lasting ≥3 hours within 48 hr after receiving a previous dose of DTP/DTaP Guillain-Barré syndrome (GBS) <6 wk after previous dose of tetanus toxoid–containing vaccine Moderate or severe acute illness with or without fever	Temperature of ≤104° F (≤40.5° C), fussiness, or mild drowsiness after a previous dose of diphtheria toxoid-tetanus toxoid-pertussis vaccine (DTP/DTaP) Family history of seizures[d] Family history of sudden infant death syndrome Family history of an adverse event after DTP or DTaP administration Stable neurologic conditions (e.g., cerebral palsy, well-controlled seizure disorder, developmental delay)
DT, Td	***Contraindication*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component ***Precautions*** GBS <6 wk after previous dose of tetanus toxoid–containing vaccine Moderate or severe acute illness with or without fever	
Tdap	***Contraindications*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component Encephalopathy (e.g., coma, decreased level of consciousness, and prolonged seizures) not attributable to another identifiable cause within 7 days of administration of previous dose of DTP, DTaP, or Tdap ***Precautions*** Moderate or severe acute illness with or without fever GBS ≤6 wk after a previous dose of tetanus-toxoid-containing vaccine Progressive or unstable neurologic disorder, uncontrolled seizures or progressive encephalopathy until a treatment regimen has been established and the condition has stabilized History of arthus-type hypersensitivity reactions following a previous dose of tetanus toxoid–containing vaccine: defer vaccination until at least 10 yr have elapsed since the last tetanus toxoid–containing vaccine	Temperature of >104° F (>40.5° C) ≤48 hours after vaccination with a previous dose of DTP or DTaP Collapse or shocklike state (i.e., hypotonic hyporesponsive episode) ≤48 hours after receiving a previous dose of DTP/DTaP Seizure ≤3 days after receiving a previous dose of DTP/DTaP[d] Persistent, inconsolable crying lasting ≥3 hours within 48 hours after receiving a previous dose of DTP/DTaP History of extensive limb swelling after DTP/DTaP/Td that is not an arthus-type reaction Stable neurologic disorder Brachial neuritis Latex allergy that is not anaphylactic Breastfeeding Immunosuppression

TABLE 5-13 Contraindications to and Precautions for Commonly Used Vaccines—cont'd

Vaccine	True Contraindications and Precautions[a]	Untrue (Vaccines Can Be Administered)
IPV	***Contraindication*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component ***Precautions*** Pregnancy Moderate or severe acute illness with or without fever	Previous receipt of one or more doses of oral polio vaccine
MMR[e]	***Contraindications*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component Pregnancy Known severe immunodeficiency (e.g., hematologic and solid tumors, receiving chemotherapy, congenital immunodeficiency, long-term immunosuppressive therapy,[f] or patients with HIV infection who are severely immunocompromised) ***Precautions*** Recent (≤11 mo) receipt of antibody-containing blood product (specific interval depends on product)[h] History of thrombocytopenia or thrombocytopenic purpura Moderate or severe acute illness with or without fever	Positive tuberculin skin test Simultaneous tuberculosis skin testing[g] Breastfeeding Pregnancy of recipient's mother or other close or household contact Recipient is female of childbearing age Immunodeficient family member or household contact Asymptomatic or mildly symptomatic HIV infection Allergy to eggs
Hib	***Contraindications*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component Age <6 wk ***Precaution*** Moderate or severe acute illness with or without fever	
Hepatitis B	***Contraindication*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component ***Precautions*** Infant weighing <2000 g[c] Moderate or severe acute illness with or without fever	Pregnancy Autoimmune disease (e.g., systemic lupus erythematosus or rheumatoid arthritis)
Hepatitis A	***Contraindication*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component ***Precautions*** Pregnancy Moderate or severe acute illness with or without fever	
Varicella	***Contraindications*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component Substantial suppression of cellular immunity Pregnancy ***Precautions*** Recent (≤11 mo) receipt of antibody-containing blood product (specific interval depends on product)[h] Moderate or severe acute illness with or without fever	Pregnancy of recipient's mother or other close or household contact Immunodeficient family member or household contact[i] Asymptomatic or mildly symptomatic HIV infection Humoral immunodeficiency (e.g., a gammaglobulinemia)[j]
PCV	***Contraindication*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component ***Precaution*** Moderate or severe acute illness with or without fever	
TIV	***Contraindication*** Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component ***Precaution*** Moderate or severe acute illness with or without fever	Nonsevere (e.g., contact) allergy to latex or thimerosal Concurrent administration of warfarin or aminophylline

Continued on following page

TABLE 5-13 Contraindications to and Precautions for Commonly Used Vaccines—cont'd

Vaccine	True Contraindications and Precautions[a]	Untrue (Vaccines Can Be Administered)
LAIV	***Contraindications***	
	Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component	
	Pregnancy	
	Known severe immunodeficiency (e.g., hematologic and solid tumors, receiving chemotherapy, congenital immunodeficiency, long-term immunosuppressive therapy,[f] or patients with HIV infection who are severely immunocompromised)	
	Previous history of GBS	
	Certain chronic medical conditions[k]	
	Precaution	
	Moderate or severe acute illness with or without fever	
PPV	***Contraindication***	History of invasive pneumococcal disease or pneumonia
	Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component	
	Precaution	
	Moderate or severe acute illness with or without fever	
MCV4	***Contraindication***	
	Severe allergic reaction (e.g., anaphylaxis) after a previous vaccine dose or to a vaccine component	
	Precautions	
	Moderate or severe acute illness with or without fever	
	History of GBS (if not at high risk for meningococcal disease)	
MPSV	***Contraindication***	
	Severe allergic reaction after a previous dose or to a vaccine component	
	Precaution	
	Moderate or severe acute illness with or without fever	
HPV	***Contraindication***	
	Severe allergic reaction after a previous dose or to a vaccine component	
	Precautions	
	Moderate or severe acute illness with or without fever	
	Pregnancy	
Rotavirus	***Contraindication***	Preterm births
	Severe allergic reaction after a previous dose or to a vaccine component	Immunosuppression in household contacts
	Precautions	Pregnant household contacts
	Moderate or severe acute illness with or without fever	
	Immunosuppression	
	Receipt of an antibody-containing blood product within 6 wk[l]	
	Preexisting gastrointestinal disease	
	Previous history of intussusception	

From Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-15), 2006.

[a]Events or conditions listed as precautions should be reviewed carefully. Benefits of and risks for administering a specific vaccine to a person under these circumstances should be considered. If the risk from the vaccine is believed to outweigh the benefit, the vaccine should not be administered. If the benefit of vaccination is believed to outweigh the risk, the vaccine should be administered. Whether and when to administer DTaP to children with proven or suspected underlying neurologic disorders should be decided on a case-by-case basis.

[b]Antibacterial drugs and mefloquine might interfere with Ty21a oral typhoid vaccine, and certain antiviral drugs might interfere with varicella-containing and live-attenuated influenza virus vaccine.

[c]Hepatitis B vaccination should be deferred for infants weighing $<$2000 g if the mother is documented to be hepatitis B surface antigen (HBsAg) negative at the time of the infant's birth. Vaccination can begin at chronologic age 1 mo. For infants born to women who are HBsAg positive, hepatitis B immunoglobulin and hepatitis B vaccine should be administered at or soon after birth regardless of weight.

[d]Acetaminophen or other appropriate antipyretic can be administered to infants and children with a history of previous seizures at the time of DTaP vaccination and every 4 hours for 24 hours thereafter to reduce the possibility of postvaccination fever. (Source: American Academy of Pediatrics: Active immunization. In Pickering LK, Baker CJ, Long SS, et al (eds): *2006 red book: report of the Committee on Infectious Diseases,* ed 27, Elk Grove Village, IL, 2006, American Academy of Pediatrics.)

[e]MMR and varicella vaccines can be administered on the same day. If not administered on the same day, these vaccines should be separated by at least 28 days.

[f]Substantially immunosuppressive steroid dose is considered to be $\geq$2 wk of daily receipt of $\geq$20 mg or $\geq$2 mg/kg body weight of prednisone or equivalent.

[g]Measles vaccination might suppress tuberculin reactivity temporarily. Measles-containing vaccine can be administered on the same day as tuberculin skin testing. If testing cannot be performed until after the day of MMR vaccination, the test should be postponed for $\geq$4 wk after the vaccination. If an urgent need exists to skin test, do so with the understanding that reactivity might be reduced by the vaccine.

[h]See text for details.

[i]If a patient experiences a presumed vaccine-related rash 7-25 days after vaccination, he or she should avoid direct contact with immunocompromised persons for the duration of the rash if possible.

[j]Vaccine should be deferred for the appropriate interval if replacement immune globulin products are being administered.

[k]For details see Centers for Disease Control and Prevention: Prevention and control of influenza: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-10), 2006.

[l]Rotavirus vaccine (RV) should be deferred for 6 wk after receipt of an antibody-containing product if possible. However, if the 6-wk deferral would cause the first dose of RV to be scheduled for age $\geq$13 wk, a shorter deferral interval should be used to ensure the first dose of RV is administered no later than age 13 wk.

TABLE 5-14 Dose and Route of Administration for Selected Vaccines

Vaccines	Dose	Route
Diphtheria, tetanus, pertussis (DTaP, DT, Td, Tdap)	0.5 ml	IM
Diphtheria, tetanus, acellular pertussis, inactivated polio, hepatitis B vaccine (DTaP-IPV-HepB)	0.5 ml	IM
Diphtheria, tetanus, acellular pertussis, *Haemophilus influenzae* type b vaccine (DTaP-Hib)	0.5 ml	IM
Haemophilus influenzae type b (Hib)	0.5 ml	IM
Haemophilus influenzae type b–Hepatitis B (Hib-HepB)	0.5 ml	IM
Hepatitis A (HepA)	≤18 yr: 0.5 ml ≥19 yr: 1.0 ml	IM
HepB	≤19 yr: 0.5 ml* ≥20 yr: 1.0 ml	IM
HepA/HepB	≥18 yr: 1.0 ml	IM
Influenza, live attenuated	0.5 ml	Intranasal spray
Influenza, trivalent inactivated	6-35 mo: 0.25 ml ≥3 yr: 0.5 ml	IM
Measles, mumps, rubella	0.5 ml	SC
Measles, mumps, rubella, varicella	0.5 ml	SC
Meningococcal conjugate	0.5 ml	IM
Meningococcal polysaccharide	0.5 ml	SC
Pneumococcal conjugate	0.5 ml	IM
Pneumococcal polysaccharide	0.5 ml	IM or SC
Human papillomavirus	0.5 ml	IM
Polio, inactivated	0.5 ml	IM or SC
Rotavirus	2.0 ml	Oral
Varicella	0.5 ml	SC
Zoster	0.7 ml	SC

From CDC: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-15), 2006. Adapted from Immunization Action Coalition (http://www.immunize.org).

IM, Intramuscularly; *SC,* subcutaneously.

*Persons aged 11-15 yr can be administered Recombivax HB (Merck) 1.0 ml (adult formulation) on a 2-dose schedule.

VACCINE ADMINISTRATION*

INFECTION CONTROL AND STERILE TECHNIQUE

Persons administering vaccines should follow appropriate precautions to minimize risk for spread of disease. Hands should be cleansed with an alcohol-based, waterless antiseptic hand rub or washed with soap and water between each patient contact. Occupational Safety and Health Administration (OSHA) regulations do not require that gloves be worn when administering vaccinations unless persons administering vaccinations are likely to come into contact with potentially infectious body fluids or have open lesions on their hands. Needles used for injections must be sterile and disposable to minimize the risk for contamination. A separate needle and syringe should be used for each injection. Changing needles between drawing vaccine from a vial and injecting it into a recipient is not necessary. Different vaccines should never be mixed in the same syringe unless specifically licensed for such use, and no attempt should be made to transfer between syringes.

For all intramuscular injections, the needle should be long enough to reach the muscle mass and prevent vaccine from seeping into subcutaneous tissue but not so long as to involve underlying nerves, blood vessels, or bone. Vaccinators should be familiar with the anatomy of the area where they are injecting vaccine. Intramuscular injections are administered at a 90-degree angle to the skin, preferably into the anterolateral aspect of the thigh or the deltoid muscle of the upper arm depending on the age of the patient.

Decision on needle size and site of injection must be made for each person on the basis of the size of the muscle, the thickness of adipose tissue at the injection site, the volume of the material to be administered, injection technique, and the depth below the muscle surface into which the material is to be injected (Fig. 5-1). Aspiration before injection of vaccines or toxoids (i.e., pulling back on the syringe plunger after needle insertion before injection) is not required because no large blood vessel exists at the recommended injection sites.

INFANTS (AGED <12 MONTHS)

For the majority of infants, the anterolateral aspect of the thigh is the recommended site for injection because it provides a large muscle mass (Fig. 5-2). The muscles of the buttock have not been used for administration of vaccines in infants and children because of concern about potential injury to the sciatic nerve, which is well documented after injection of antimicrobial agents into the buttock. If the gluteal muscle must be used, care should be taken to define the anatomic landmarks.† Injection technique is the most important parameter to ensure efficient intramuscular vaccine delivery. If the subcutaneous and muscle tissue are bunched to minimize the chance of striking bone, a 1-inch needle is required to ensure intramuscular administration in infants. For the majority of infants, a 1-inch, 22- to 25-gauge needle is sufficient to penetrate muscle in an infant's thigh. For newborn (first 28 days of life) and premature infants, a ⅝-inch-long needle usually is adequate if the skin is stretched flat between thumb and forefinger and the needle inserted at a 90-degree angle to the skin.

FIGURE 5-2 Intramuscular/subcutaneous site of administration: anterolateral thigh. (Adapted from Minnesota Department of Health. In Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices [ACIP], *MMWR* 55[RR-15]:6, 2006.)

TODDLERS AND OLDER CHILDREN (AGED 12 MONTHS TO 10 YEARS)

The deltoid muscle should be used if the muscle mass is adequate. The needle size for deltoid site injections can range from 22 to 25 gauge and from ⅝ to 1 inch on the basis of the size of the muscle and the thickness of adipose tissue at the injection site (Fig. 5-3). A ⅝-inch needle is adequate only for the deltoid muscle and only if the skin is stretched flat between the thumb and forefinger and the needle inserted at a 90-degree

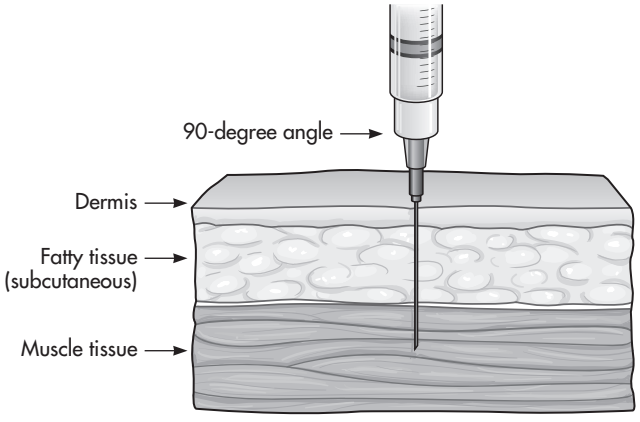

FIGURE 5-1 Intramuscular needle insertion. (Adapted from California Immunization Branch. In Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices [ACIP], *MMWR* 55[RR-15]:16, 2006.)

FIGURE 5-3 Intramuscular site of administration: deltoid. (Adapted from Minnesota Department of Health. In Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices [ACIP], *MMWR* 55[RR-15]:17, 2006.)

*From Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-15):14-16, 2006.

†If the gluteal muscle is chosen, injection should be administered lateral and superior to a line between the posterior superior iliac spine and the greater trochanter or in the ventrogluteal site, the center of a triangle bounded by the anterior superior iliac spine, the tubercle of the iliac crest, and the upper border of the greater trochanter.

angle to the skin. For toddlers, the anterolateral thigh can be used, but the needle should be at least 1 inch in length.

ADOLESCENTS AND ADULTS (AGED >11 YEARS)

For adults and adolescents, the deltoid muscle is recommended for routine intramuscular vaccinations. The anterolateral thigh also can be used. For men and women weighing <130 lb (<60 kg) a ⅝- to 1-inch needle is sufficient to ensure intramuscular injection. For women weighing 130 to 200 lb (60 to 90 kg) and men 130 to 260 lb (60 to 118 kg), a 1- to 1½-inch needle is needed. For women weighing >200 lb (>90 kg) or men weighing >260 lb (>118 kg), a 1½-inch needle is required.

SUBCUTANEOUS INJECTIONS

Subcutaneous injections are administered at a 45-degree angle, usually into the thigh for infants younger than 12 months and in the upper-outer triceps area of persons aged 12 months and older. Subcutaneous injections can be administered into the upper-outer triceps area of an infant if necessary. A ⅝-inch, 23- to 25-gauge needle should be inserted into the subcutaneous tissue (Figs. 5-4 and 5-5).

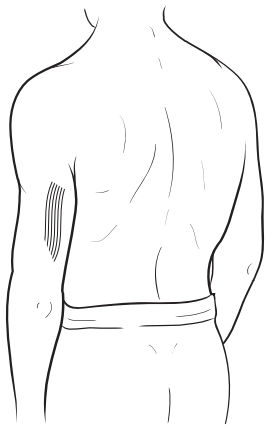

FIGURE 5-4 Subcutaneous site of administration: triceps. (Adapted from Minnesota Department of Health. In Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices [ACIP], *MMWR* 55[RR-15]:17, 2006.)

TABLE 5-15 Treatment of Anaphylaxis with Intramuscular or Oral Pharmaceuticals

Drug	Dosage
Child	
Primary regimen	
Epinephrine 1:1000 (aqueous) (1 mg/ml)*	0.01 mg/kg up to 0.5 mg (administer 0.01 ml/kg/dose up to 0.5 ml) IM repeated every 10-20 min up to 3 doses
Secondary regimen	
Diphenhydramine	1-2 mg/kg oral, IM or IV, every 4-6 hr (maximum single dose: 100 mg)
Hydroxyzine	0.5-1 mg/kg oral, IM, every 4-6 hr (maximum single dose: 100 mg)
Prednisone	1.5-2 mg/kg oral (maximum single dose: 60 mg); use corticosteroids as long as needed
Adult	
Primary regimen	
Epinephrine 1:1000 (aqueous)*	0.01 mg/kg up to 0.5 mg (give 0.01 ml/kg/dose up to 0.5 ml) IM repeated every 10-20 min up to 3 doses
Secondary regimen	
Diphenhydramine	1-2 mg/kg up to 100 mg IM or oral every 4-6 hr

From Centers for Disease Control and Prevention: General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-15), 2006. Adapted from American Academy of Pediatrics: Passive immunization. In Pickering LK, Baker CJ, Long SS, et al (eds): *Red book: 2006 report of the Committee on Infectious Diseases,* ed 27, Elk Grove, IL, 2006, American Academy of Pediatrics; and Immunization Action Coalition: Medical management of anaphylaxis in adult patients. Available at http://www.immunize.org/catg.d/p3082.pdf, and Mosby's Drug Consult 2005.

IM, Intramuscularly; *IV,* intravenously.

*If agent causing anaphylactic reaction was administered by injection, epinephrine can be injected into the same site to slow absorption.

TABLE 5-16 Vaccination of Persons with Primary and Secondary Immune Deficiencies

Category	Specific Immunodeficiency	Vaccines Contraindicated*	Risk-Specific Vaccines Recommended*	Effectiveness and Comments
		PRIMARY		
B-lymphocyte (humoral)	Severe antibody deficiencies (e.g., X-linked agammaglobulinemia and common variable immunodeficiency)	Oral poliovirus (OPV)† Smallpox Live-attenuated influenza vaccine (LAIV) BCG Live oral typhoid (Ty21a)	Pneumococcal Influenza (TIV) Consider measles and varicella vaccination	The effectiveness of any vaccine will be uncertain if it depends only on the humoral response; IV immune globulin interferes with the immune response to measles vaccine and possibly varicella vaccine
	Less severe antibody deficiencies (e.g., selective IgA deficiency and IgG subclass deficiency)	OPV† Other live vaccines appear to be safe	Pneumococcal influenza (TIV)	All vaccines probably effective; immune response may be attenuated
T-lymphocyte (cell mediated and humoral)	Complete defects (e.g., severe combined immunodeficiency [SCID] disease, complete DiGeorge syndrome)	All live vaccines‡§	Pneumococcal influenza (TIV)	Vaccines may be ineffective
	Partial defects (e.g., the majority of patients with DiGeorge syndrome, Wiskott-Aldrich syndrome, ataxia-telangiectasia)	All live vaccines‡§	Pneumococcal Meningococcal *Haemophilus influenza* type b (Hib) (if not administered in infancy) Influenza (TIV)	Effectiveness of any vaccine depends on degree of immune suppression
Complement	Deficiency of early components (C1, C2, C3, and C4)	None	Pneumococcal Meningococcal Influenza (TIV)	All routine vaccines probably effective
	Deficiency of late components (C5-C9) and C3, properdin, factor B	None	Pneumococcal Meningococcal Influenza (TIV)	All routine vaccines probably effective
Phagocytic function	Chronic granulomatous disease, leukocyte adhesion defect, and myeloperoxidase deficiency	Live bacterial vaccines‡	Pneumococcal‖ Influenza (TIV) (to decrease secondary bacterial infection)	All inactivated vaccines safe and probably effective Live viral vaccines probably safe and effective
		SECONDARY		
	HIV/AIDS	OPV Smallpox BCG LAIV Withhold MMR and varicella in severely immunocompromised persons	Influenza (TIV) Pneumococcal Consider Hib (if not administered in infancy) and meningococcal vaccination	Measles, mumps, rubella (MMR); varicella; and all inactivated vaccines, including inactivated influenza, might be effective¶
	Malignant neoplasm, transplantation, immunosuppressive or radiation therapy	Live viral and bacterial, depending on immune status	Influenza (TIV) Pneumococcal	Effectiveness of any vaccine depends on degree of immune suppression
	Asplenia	None	Pneumococcal Meningococcal Hib (if not administered in infancy)	All routine vaccines probably effective
	Chronic renal disease	LAIV	Pneumococcal Influenza (TIV) Hepatitis B	All routine vaccines probably effective

From Centers for Disease Control and Prevention (CDC): General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-15), 2006. Modified from American Academy of Pediatrics: Passive immunization. In Pickering LK, Baker CJ, Long SS, et al (eds): *Red book: 2006 report of the Committee on Infectious Diseases,* ed 27, Elk Grove, IL, 2006, American Academy of Pediatrics; and CDC: Use of vaccines and immune globulins in persons with altered immunocompetence: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 42(RR-4):42, 1993.

BCG, Bacille Calmette-Guérin; *Ig,* immunoglobulin; *IV,* intravenous.

*Other vaccines that are universally or routinely recommended should be administered if not contraindicated.

†OPV is no longer available for routine use in the United States.

‡Live bacterial vaccines: BCG and Ty21a *Salmonella typhi* vaccine.

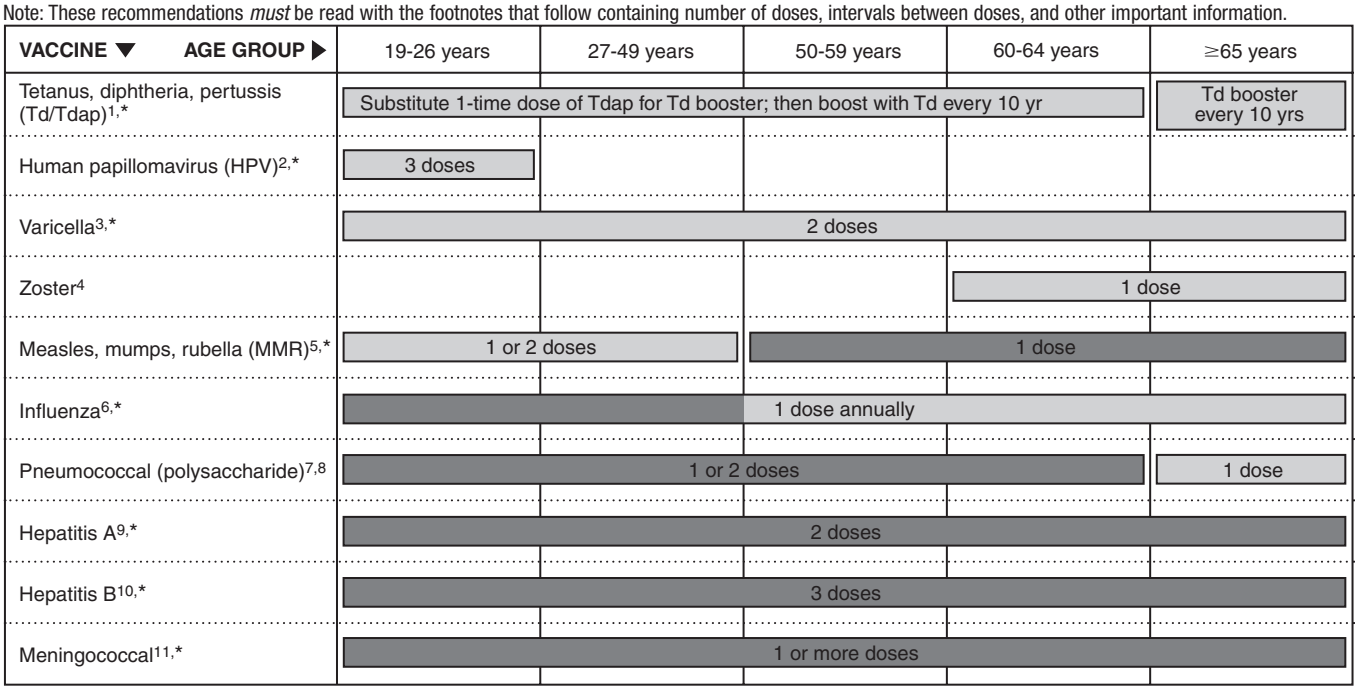
§Live viral vaccines: MMR, OPV, LAIV, yellow fever, and varicella, including measles-mumps-rubella-varicella (MMRV) and herpes zoster (HZ) vaccine, and vaccinia (smallpox). Smallpox vaccine is not recommended for children or the general public.

‖Pneumococcal vaccine is not indicated for children with chronic granulomatous disease.

¶Children infected with HIV should receive IG after exposure to measles and can receive varicella and measles vaccine if CD4+ lymphocyte count is >15%.

TABLE 5-17 Approaches to the Evaluation and Vaccination of Internationally Adopted Children with No or Questionable Vaccination Records

Vaccine	Recommended Approach	Alternative Approach
Measles, mumps, and rubella (MMR)	Revaccinate with MMR	Serologic testing for immunoglobulin G (IgG) antibody to measles, mumps, and rubella
Haemophilus influenzae type b (Hib)	Age-appropriate revaccination	—
Hepatitis A	Age-appropriate revaccination	Serologic testing for IgG antibody to hepatitis A virus
Hepatitis B (Hep B)	Age-appropriate revaccination and serologic testing for HBsAg*	—
Poliovirus	Revaccinate with inactivated poliovirus vaccine (IPV)	Serologic testing for neutralizing antibody to poliovirus types 1, 2, and 3 (limited availability)
Diphtheria and tetanus toxoids and acellular pertussis (DTaP)	Revaccination with DTaP, with serologic testing for specific IgG antibody to tetanus and diphtheria toxins in the event of a severe local reaction	Children whose records indicate receipt of ≥3 doses: serologic testing for specific IgG antibody to diphtheria and tetanus toxins before administering additional doses or administer a single booster dose of DTaP, followed by serologic testing after 1 mo for specific IgG antibody to diphtheria and tetanus toxins with revaccination as appropriate
Varicella	Age-appropriate vaccination of children who lack evidence of varicella immunity	—
Pneumococcal conjugate	Age-appropriate vaccination	—



From Centers for Disease Control and Prevention (CDC): General recommendations on immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55:(RR-15), 2006.

*Very rarely, Hep B vaccine can give a false-positive hepatitis B surface antigen (HBsAg) result up to 18 days after vaccination; therefore blood should be drawn to test for HBsAg before vaccinating. (Source: CDC: A comprehensive immunization strategy to eliminate transmission of hepatitis B virus infection in the United States: recommendations of the Advisory Committee on Immunization Practices [ACIP]; Part I: immunization in infants, children, and adolescents, *MMWR* 54[RR-16], 2005.)

Immunizations for Adults

TABLE 5-18 Recommended Adult Immunization Schedule, by Vaccine and Age Group—United States

Note: These recommendations *must* be read with the footnotes that follow containing number of doses, intervals between doses, and other important information.

*Covered by the Vaccine Injury Compensation Program.

For all persons in this category who meet the age requirements and who lack evidence of immunity (e.g., lack documentation of vaccination or have no evidence of prior infection)

Recommended if some other risk factor is present (e.g., on the basis of medical, occupational, lifestyle, or other indications)

No recommendation

*These schedules indicate the recommended age groups and medical indications for which administration of currently licensed vaccines is commonly indicated for adults ages 19 years and older, as of January 1, 2010. Licensed combination vaccines may be used whenever any components of the combination are indicated and when the vaccine's other components are not contraindicated. For detailed recommendations on all vaccines, including those used primarily for travelers or that are issued during the year, consult the manufacturers' package inserts and the complete statements from the Advisory Committee on Immunization Practices (http://www.cdc.gov/vaccines/pubs/acip-list.htm).

Report all clinically significant postvaccination reactions to the Vaccine Adverse Event Reporting System (VAERS). Reporting forms and instructions on filing a VAERS report are available at www.vaers.hhs.gov or by telephone, 800-822-7967.

Information on how to file a Vaccine Injury Compensation Program claim is available at www.hrsa.gov/vaccinecompensation or by telephone, 800-338-2382. To file a claim for vaccine injury, contact the U.S. Court of Federal Claims, 717 Madison Place, N.W., Washington, D.C. 20005; telephone, 202-357-6400.

Additional information about the vaccines in this schedule, extent of available data, and contraindications for vaccination is also available at www.cdc.gov/vaccines or from the CDC-INFO Contact Center at 800-CDC-INFO (800-232-4636) in English and Spanish, 24 hours a day, 7 days a week.

Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

[1]Tetanus, diphtheria, and acellular pertussis (Td/Tdap) vaccination

Tdap should replace a single dose of Td for adults aged 19 through 64 yr who have not received a dose of Tdap previously.

Adults with uncertain or incomplete history of primary vaccination series with tetanus and diphtheria toxoid–containing vaccines should begin or complete a primary vaccination series. A primary series for adults is 3 doses of tetanus and diphtheria toxoid–containing vaccines; administer the first 2 doses at least 4 wk apart and the third dose 6-12 mo after the second. However, Tdap can substitute for any one of the doses of Td in the 3-dose primary series. The booster dose of tetanus and diphtheria toxoid–containing vaccine should be administered to adults who have completed a primary series and if the last vaccination was received 10 or more yr previously. Tdap or Td vaccine may be used, as indicated.

If a woman is pregnant and received the last Td vaccination 10 or more yr previously, administer Td during the second or third trimester. If the woman received the last Td vaccination less than 10 yr previously, administer Tdap during the immediate postpartum period. A dose of Tdap is recommended for postpartum women, close contacts of infants age less than 12 mo, and all health care personnel with direct patient contact if they have not previously received Tdap. An interval as short as 2 yr from the last Td is suggested; shorter intervals can be used. Td may be deferred during pregnancy and Tdap substituted in the immediate postpartum period, or Tdap may be administered instead of Td to a pregnant woman after an informed discussion with the woman.

Consult the ACIP statement for recommendations for administering Td as prophylaxis in wound management.

[2]Human papillomavirus (HPV) vaccination

HPV vaccination is recommended for all females and males aged 11 through 26 yr (and may begin at age 9 yr) who have not completed the vaccine series. History of genital warts, abnormal Papanicolaou test result, or positive HPV DNA test result is not evidence of prior infection with all vaccine HPV types; HPV vaccination is recommended for persons with such histories.

Ideally, vaccine should be administered before potential exposure to HPV through sexual activity; however, persons who are sexually active should still be vaccinated consistent with age-based recommendations. Sexually active persons who have not been infected with any of the 4 HPV vaccine types receive the full benefit of the vaccination. Vaccination is less beneficial for persons who have already been infected with 1 or more of the HPV vaccine types.

A complete series consists of 3 doses. The second dose should be administered 2 mo after the first dose; the third dose should be administered 6 mo after the first dose.

HPV vaccination is not specifically recommended for persons with the medical indications described in Table 5-19. Because it is not a live-virus vaccine, it can be administered to persons with the medical indications noted. However, the immune response and vaccine efficacy might be less for persons with the noted medical indications than in persons who do not have the medical indications described or who are immunocompetent. Health care personnel are not at increased risk because of occupational exposure and should be vaccinated consistent with age-based recommendations.

HPV4 may be given to males aged 9 through 26 years to reduce the likelihood of acquiring genital warts.

HPV4 would be most effective when given before exposure to HPV through sexual contact.

[3]Varicella vaccination

All adults without evidence of immunity to varicella should receive 2 doses of single-antigen varicella vaccine if not previously vaccinated or the second dose if they have received only 1 dose, unless they have a medical contraindication. Special consideration should be given to those who 1) have close contact with persons at high risk for severe disease (e.g., health care personnel and family contacts of persons with immunocompromising conditions) or 2) are at high risk for exposure or transmission (e.g., teachers; child care employees; residents and staff members of institutional settings, including correctional institutions; college students; military personnel; adolescents and adults living in households with children; nonpregnant women of childbearing age; and international travelers).

Evidence of immunity to varicella in adults includes any of the following: 1) documentation of 2 doses of varicella vaccine at least 4 wk apart; 2) U.S.-born before 1980 (although for health care personnel and pregnant women, birth before 1980 should not be considered evidence of immunity); 3) history of varicella based on diagnosis or verification of varicella by a health care provider (for a patient reporting a history of or presenting with an atypical case, a mild case, or both, health care providers should seek either an epidemiologic link to a typical varicella case or to a laboratory-confirmed case or evidence of laboratory confirmation, if it was performed at the time of acute disease); 4) history of herpes zoster based on health care provider diagnosis or verification of herpes zoster by a health care provider; or 5) laboratory evidence of immunity or laboratory confirmation of disease.

TABLE 5-18 Recommended Adult Immunization Schedule, by Vaccine and Age Group—United States—cont'd

Pregnant women should be assessed for evidence of varicella immunity. Women who do not have evidence of immunity should receive the first dose of varicella vaccine upon completion or termination of pregnancy and before discharge from the health care facility. The second dose should be administered 4-8 wk after the first dose.

[4]Herpes zoster vaccination

A single dose of zoster vaccine is recommended for adults aged 60 yr and older regardless of whether they report a prior episode of herpes zoster. Persons with chronic medical conditions may be vaccinated unless their condition constitutes a contraindication.

[5]Measles, mumps, rubella (MMR) vaccination

Measles component: Adults born before 1957 generally are considered immune to measles. Adults born during or after 1957 should receive 1 or more doses of MMR unless they have a medical contraindication, documentation of 1 or more doses, history of measles based on health care provider diagnosis, or laboratory evidence of immunity.

A second dose of MMR is recommended for adults who 1) have been recently exposed to measles or are in an outbreak setting; 2) have been vaccinated previously with killed measles vaccine; 3) have been vaccinated with an unknown type of measles vaccine during 1963-1967; 4) are students in postsecondary educational institutions; 5) work in a health care facility; or 6) plan to travel internationally.

Mumps component: Adults born before 1957 generally are considered immune to mumps. Adults born during or after 1957 should receive 1 dose of MMR unless they have a medical contraindication, history of mumps based on health care provider diagnosis, or laboratory evidence of immunity.

A second dose of MMR is recommended for adults who 1) live in a community experiencing a mumps outbreak and are in an affected age group; 2) are students in postsecondary educational institutions; 3) work in a health care facility; or 4) plan to travel internationally. For unvaccinated health care personnel born before 1957 who do not have other evidence of mumps immunity, administering 1 dose on a routine basis should be considered and administering a second dose during an outbreak should also be strongly considered.

Rubella component: 1 dose of MMR vaccine is recommended for women whose rubella vaccination history is unreliable or who lack laboratory evidence of immunity. For women of childbearing age, regardless of birth yr, rubella immunity should be determined and women should be counseled regarding congenital rubella syndrome. Women who do not have evidence of immunity should receive MMR vaccine upon completion or termination of pregnancy and before discharge from the health care facility.

[6]Influenza vaccination

Medical indications: Chronic disorders of the cardiovascular or pulmonary systems, including asthma; chronic metabolic diseases, including diabetes mellitus, renal or hepatic dysfunction, hemoglobinopathies, or immunocompromising conditions (including immunocompromising conditions caused by medications or HIV); any condition that compromises respiratory function or the handling of respiratory secretions or that can increase the risk of aspiration (e.g., cognitive dysfunction, spinal cord injury, or seizure disorder or other neuromuscular disorder); and pregnancy during the influenza season. No data exist on the risk for severe or complicated influenza disease among persons with asplenia; however, influenza is a risk factor for secondary bacterial infections that can cause severe disease among persons with asplenia.

Occupational indications: All health care personnel, including those employed by long-term care and assisted-living facilities, and caregivers of children younger than 5 yr.

Other indications: Residents of nursing homes and other long-term care and assisted-living facilities; persons likely to transmit influenza to persons at high risk (e.g., in-home household contacts and caregivers of children younger than 5 yr, persons 65 yr and older, and persons of all ages with high-risk condition[s]); and anyone who would like to decrease their risk of getting influenza. Healthy, nonpregnant adults younger than 50 yr without high-risk medical conditions who are not contacts of severely immunocompromised persons in special care units can receive either intranasally administered live, attenuated influenza vaccine (FluMist) or inactivated vaccine. Other persons should receive the inactivated vaccine.

[7]Pneumococcal polysaccharide (PPSV) vaccination

Medical indications: Chronic lung disease (including asthma); chronic cardiovascular diseases; diabetes mellitus; chronic liver diseases, cirrhosis; chronic alcoholism, chronic renal failure, or nephrotic syndrome; functional or anatomic asplenia (e.g., sickle cell disease or splenectomy [if elective splenectomy is planned, vaccinate at least 2 wk before surgery]); immunocompromising conditions; and cochlear implants and cerebrospinal fluid leaks. Vaccinate as close to HIV diagnosis as possible.

Other indications: Residents of nursing homes or other long-term care facilities and persons who smoke cigarettes. Routine use of PPSV is not recommended for Alaska Native or American Indian persons younger than 65 yr unless they have underlying medical conditions that are PPSV indications. However, public health authorities may consider recommending PPSV for Alaska Natives and American Indians 50 through 64 yr of age who are living in areas in which the risk of invasive pneumococcal disease is increased.

[8]Revaccination with PPSV

One-time revaccination after 5 yr for persons with chronic renal failure or nephrotic syndrome, functional or anatomic asplenia (e.g., sickle cell disease or splenectomy), and persons with immunocompromising conditions. For persons aged 65 yr or older, 1-time revaccination if they were vaccinated 5 or more yr previously and were younger than 65 yr at the time of primary vaccination.

[9]Hepatitis A vaccination

Medical indications: Persons with chronic liver disease and persons who receive clotting factor concentrates.

Behavioral indications: Men who have sex with men and persons who use illegal drugs.

Occupational indications: Persons working with hepatitis A virus (HAV)–infected primates or with HAV in a research laboratory setting.

Other indications: Persons traveling to or working in countries that have high or intermediate endemicity of hepatitis A (a list of countries is available at wwwn.cdc.gov/travel/contentdiseases.aspx) and any person seeking protection from HAV infection. Unvaccinated persons who anticipate close personal contact (e.g., household contact or regular babysitting) with an international adoptee from a country of high or intermediate endemicity during the first 60 days following arrival of the adoptee in the United States should consider vaccination. The first dose of the 2-dose HepA series should be administered as soon as adoption is planned, ideally 2 or more weeks before the arrival of the adoptee.

Single-antigen vaccine formulations should be administered in a 2-dose schedule at either 0 and 6-12 mo (Havrix) or 0 and 6-18 mo (Vaqta). If the combined hepatitis A and hepatitis B vaccine (Twinrix) is used, administer 3 doses at 0, 1, and 6 mo; alternatively, a 4-dose schedule, administered on days 0, 7, and 21 to 30 followed by a booster dose at mo 12 may be used.

[10]Hepatitis B vaccination

Medical indications: Persons with end-stage renal disease, including patients receiving hemodialysis; persons with HIV infection; and persons with chronic liver disease.

Occupational indications: Health care personnel and public-safety workers who are exposed to blood or other potentially infectious body fluids.

Behavioral indications: Sexually active persons who are not in a long-term, mutually monogamous relationship (e.g., persons with more than 1 sex partner during the previous 6 mo); persons seeking evaluation or treatment for a sexually transmitted disease (STD); current or recent injection-drug users; and men who have sex with men.

Other indications: Household contacts and sex partners of persons with chronic hepatitis B virus (HBV) infection; clients and staff members of institutions for persons with developmental disabilities; international travelers to countries with high or intermediate prevalence of chronic HBV infection (a list of countries is available at wwwn.cdc.gov/travel/contentdiseases.aspx); and any adult seeking protection from HBV infection.

Hepatitis B vaccination is recommended for all adults in the following settings: STD treatment facilities, HIV testing and treatment facilities, facilities providing drug-abuse treatment and prevention services, health care settings targeting services to injection-drug users or men who have sex with men, correctional facilities, end-stage renal disease programs and facilities for chronic hemodialysis patients, and institutions and nonresidential day care facilities for persons with developmental disabilities.

If the combined hepatitis A and hepatitis B vaccine (Twinrix) is used, administer 3 doses at 0, 1, and 6 mo; alternatively, a 4-dose schedule, administered on days 0, 7, and 21 to 30 followed by a booster dose at mo 12 may be used.

Special formulation indications: For adult patients receiving hemodialysis or with other immunocompromising conditions, 1 dose of 40 μg/ml (Recombivax HB) administered on a 3-dose schedule or 2 doses of 20 μg/mL (Engerix-B) administered simultaneously on a 4-dose schedule at 0, 1, 2, and 6 mo.

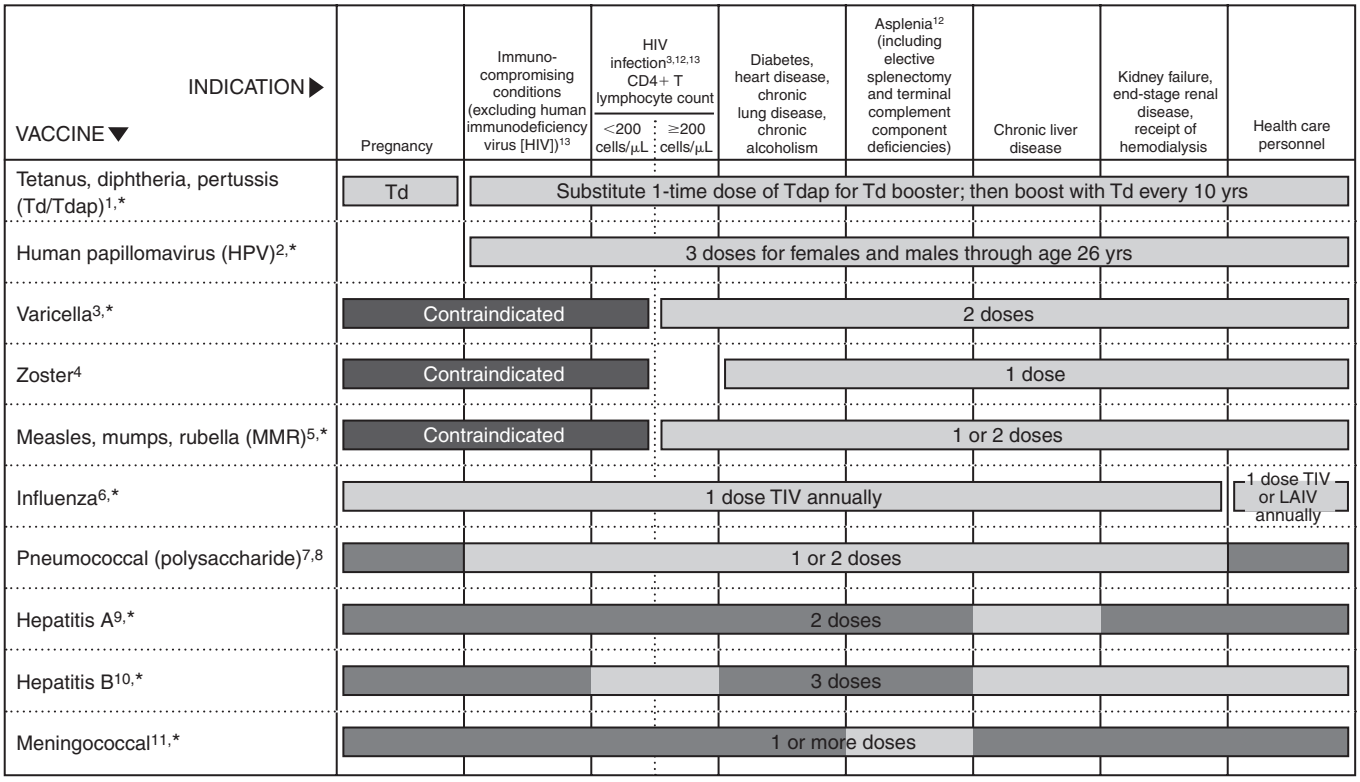
[11]Meningococcal vaccination

Medical indications: Adults with anatomic or functional asplenia or terminal complement component deficiencies.

Other indications: First-yr college students living in dormitories; microbiologists who are routinely exposed to isolates of *Neisseria* meningitidis; military recruits; and persons who travel to or live in countries in which meningococcal disease is hyperendemic or epidemic (e.g., the "meningitis belt" of sub-Saharan Africa during the dry season [December-June]), particularly if their contact with local populations will be prolonged. Vaccination is required by the government of Saudi Arabia for all travelers to Mecca during the annual Hajj.

Meningococcal conjugate vaccine (MCV4) is preferred for adults aged 56 years and older. Revaccination with MCV4 after 5 years is recommended for adults previously vaccinated with MCV4 or MPSV4 who remain at increased risk for infection (e.g., adults with anatomic or functional asplenia). Persons whose only risk factor is living in on-campus housing are not recommended to receive an additional dose.

[12]Selected conditions for which Haemophilus influenzae type b (Hib) vaccine may be used



Hib vaccine generally is not recommended for persons aged 5 years and older. No efficacy data are available on which to base a recommendation concerning use of Hib vaccine for older children and adults. However, studies suggest good immunogenicity in patients who have sickle cell disease, leukemia, or HIV infection or who have had a splenectomy; administering 1 dose of vaccine to these patients is not contraindicated.

[13]Immunocompromising conditions

Inactivated vaccines generally are acceptable (e.g., pneumococcal, meningococcal, and influenza [trivalent inactive influenza vaccine]) and live vaccines generally are avoided in persons with immune deficiencies or immuno-compromising conditions. Information on specific conditions is available at http://www.cdc.gov/vaccines/pubs/acip-list.htm.

TABLE 5-19 Vaccines That Might Be Indicated for Adults Based on Medical and Other Indications—United States

Note: These recommendations *must* be read with the footnotes that follow containing number of doses, intervals between doses, and other important information.

These schedules indicate the recommended age groups and medical indications for which administration of currently licensed vaccines is commonly indicated for adults ages 19 years and older. Licensed combination vaccines may be used whenever any components of the combination are indicated and when the vaccine's other components are not contraindicated. For detailed recommendations on all vaccines, including those used primarily for travelers or that are issued during the year, consult the manufacturers' package inserts and the complete statements from the Advisory Committee on Immunization Practices (http://www.cdc.gov/vaccines/pubs/acip-list.htm).

[1]Tetanus, diphtheria, and acellular pertussis (Td/Tdap) vaccination

Tdap should replace a single dose of Td for adults aged 19 through 64 yr who have not received a dose of Tdap previously.

Adults with uncertain or incomplete history of primary vaccination series with tetanus and diphtheria toxoid–containing vaccines should begin or complete a primary vaccination series. A primary series for adults is 3 doses of tetanus and diphtheria toxoid–containing vaccines; administer the first 2 doses at least 4 wk apart and the third dose 6-12 mo after the second. However, Tdap can substitute for any one of the doses of Td in the 3-dose primary series. The booster dose of tetanus and diphtheria toxoid–containing vaccine should be administered to adults who have completed a primary series and if the last vaccination was received 10 or more yr previously. Tdap or Td vaccine may be used, as indicated.

If a woman is pregnant and received the last Td vaccination 10 or more yr previously, administer Td during the second or third trimester. If the woman received the last Td vaccination less than 10 yr previously, administer Tdap during the immediate postpartum period. A dose of Tdap is recommended for postpartum women, close contacts of infants age less than 12 mo, and all health care personnel with direct patient contact if they have not previously received Tdap. An interval as short as 2 yr from the last Td is suggested; shorter intervals can be used. Td may be deferred during pregnancy and Tdap substituted in the immediate postpartum period, or Tdap may be administered instead of Td to a pregnant woman after an informed discussion with the woman.

Consult the ACIP statement for recommendations for administering Td as prophylaxis in wound management.

[2]Human papillomavirus (HPV) vaccination

HPV vaccination is recommended for all females and males aged 11 through 26 yr (and may begin at age 9 yr) who have not completed the vaccine series. History of genital warts, abnormal Papanicolaou test result, or positive HPV DNA test result is not evidence of prior infection with all vaccine HPV types; HPV vaccination is recommended for persons with such histories.

Ideally, vaccine should be administered before potential exposure to HPV through sexual activity; however, persons who are sexually active should still be vaccinated consistent with age-based recommendations. Sexually active persons who have not been infected with any of the 4 HPV vaccine types receive the full benefit of the vaccination. Vaccination is less beneficial for persons who have already been infected with 1 or more of the HPV vaccine types.

A complete series consists of 3 doses. The second dose should be administered 2 mo after the first dose; the third dose should be administered 6 mo after the first dose.

HPV vaccination is not specifically recommended for persons with the medical indications described in Table 5-19. Because it is not a live-virus vaccine, it can be administered to persons with the medical indications noted. However, the immune response and vaccine efficacy might be less for persons with the noted medical indications than in persons who do not have the medical indications described or who are immunocompetent. Health care personnel are not at increased risk because of occupational exposure and should be vaccinated consistent with age-based recommendations.

[3]Varicella vaccination

All adults without evidence of immunity to varicella should receive 2 doses of single-antigen varicella vaccine if not previously vaccinated or the second dose if they have received only 1 dose, unless they have a medical contraindication. Special consideration should be given to those who 1) have close contact with persons at high risk for severe disease (e.g., health care personnel and family contacts of persons with immunocompromising conditions) or 2) are at high risk for exposure or transmission (e.g., teachers; child care employees; residents and staff members of institutional settings, including correctional institutions; college students; military personnel; adolescents and adults living in households with children; nonpregnant women of childbearing age; and international travelers).

Evidence of immunity to varicella in adults includes any of the following: 1) documentation of 2 doses of varicella vaccine at least 4 wk apart; 2) U.S.-born before 1980 (although for health care personnel and pregnant women, birth before 1980 should not be considered evidence of immunity); 3) history of varicella based on diagnosis or verification of varicella by a health care provider (for a patient reporting a history of or presenting with an atypical case, a mild case, or both, health care providers should seek either an epidemiologic link to a typical varicella case or to a laboratory-confirmed case or evidence of laboratory confirmation, if it was performed at the time of acute disease); 4) history of herpes zoster based on health care provider diagnosis or verification of herpes zoster by a health care provider; or 5) laboratory evidence of immunity or laboratory confirmation of disease.

Pregnant women should be assessed for evidence of varicella immunity. Women who do not have evidence of immunity should receive the first dose of varicella vaccine upon completion or termination of pregnancy and before discharge from the health care facility. The second dose should be administered 4-8 wk after the first dose.

TABLE 5-19 Vaccines That Might Be Indicated for Adults Based on Medical and Other Indications—United States—cont'd

[4]Herpes zoster vaccination

A single dose of zoster vaccine is recommended for adults aged 60 yr and older regardless of whether they report a prior episode of herpes zoster. Persons with chronic medical conditions may be vaccinated unless their condition constitutes a contraindication.

[5]Measles, mumps, rubella (MMR) vaccination

Measles component: Adults born before 1957 generally are considered immune to measles. Adults born during or after 1957 should receive 1 or more doses of MMR unless they have a medical contraindication, documentation of 1 or more doses, history of measles based on health care provider diagnosis, or laboratory evidence of immunity.

A second dose of MMR is recommended for adults who 1) have been recently exposed to measles or are in an outbreak setting; 2) have been vaccinated previously with killed measles vaccine; 3) have been vaccinated with an unknown type of measles vaccine during 1963-1967; 4) are students in postsecondary educational institutions; 5) work in a health care facility; or 6) plan to travel internationally.

Mumps component: Adults born before 1957 generally are considered immune to mumps. Adults born during or after 1957 should receive 1 dose of MMR unless they have a medical contraindication, history of mumps based on health care provider diagnosis, or laboratory evidence of immunity.

A second dose of MMR is recommended for adults who 1) live in a community experiencing a mumps outbreak and are in an affected age group; 2) are students in postsecondary educational institutions; 3) work in a health care facility; or 4) plan to travel internationally. For unvaccinated health care personnel born before 1957 who do not have other evidence of mumps immunity, administering 1 dose on a routine basis should be considered and administering a second dose during an outbreak should also be strongly considered.

Rubella component: 1 dose of MMR vaccine is recommended for women whose rubella vaccination history is unreliable or who lack laboratory evidence of immunity. For women of childbearing age, regardless of birth yr, rubella immunity should be determined and women should be counseled regarding congenital rubella syndrome. Women who do not have evidence of immunity should receive MMR vaccine upon completion or termination of pregnancy and before discharge from the health care facility.

[6]Influenza vaccination

Medical indications: Chronic disorders of the cardiovascular or pulmonary systems, including asthma; chronic metabolic diseases, including diabetes mellitus, renal or hepatic dysfunction, hemoglobinopathies, or immunocompromising conditions (including immunocompromising conditions caused by medications or HIV); any condition that compromises respiratory function or the handling of respiratory secretions or that can increase the risk of aspiration (e.g., cognitive dysfunction, spinal cord injury, or seizure disorder or other neuromuscular disorder); and pregnancy during the influenza season. No data exist on the risk for severe or complicated influenza disease among persons with asplenia; however, influenza is a risk factor for secondary bacterial infections that can cause severe disease among persons with asplenia.

Occupational indications: All health care personnel, including those employed by long-term care and assisted-living facilities, and caregivers of children younger than 5 yr.

Other indications: Residents of nursing homes and other long-term care and assisted-living facilities; persons likely to transmit influenza to persons at high risk (e.g., in-home household contacts and caregivers of children younger than 5 yr, persons 65 yr and older, and persons of all ages with high-risk condition[s]); and anyone who would like to decrease their risk of getting influenza. Healthy, nonpregnant adults younger than 50 yr without high-risk medical conditions who are not contacts of severely immunocompromised persons in special care units can receive either intranasally administered live, attenuated influenza vaccine (FluMist) or inactivated vaccine. Other persons should receive the inactivated vaccine.

[7]Pneumococcal polysaccharide (PPSV) vaccination

Medical indications: Chronic lung disease (including asthma); chronic cardiovascular diseases; diabetes mellitus; chronic liver diseases, cirrhosis; chronic alcoholism, chronic renal failure, or nephrotic syndrome; functional or anatomic asplenia (e.g., sickle cell disease or splenectomy [if elective splenectomy is planned, vaccinate at least 2 wk before surgery]); immunocompromising conditions; and cochlear implants and cerebrospinal fluid leaks. Vaccinate as close to HIV diagnosis as possible.

Other indications: Residents of nursing homes or other long-term care facilities and persons who smoke cigarettes. Routine use of PPSV is not recommended for Alaska Native or American Indian persons younger than 65 yr unless they have underlying medical conditions that are PPSV indications. However, public health authorities may consider recommending PPSV for Alaska Natives and American Indians 50 through 64 yr of age who are living in areas in which the risk of invasive pneumococcal disease is increased.

[8]Revaccination with PPSV

One-time revaccination after 5 yr for persons with chronic renal failure or nephrotic syndrome, functional or anatomic asplenia (e.g., sickle cell disease or splenectomy), and persons with immunocompromising conditions. For persons age 65 yr or older, 1-time revaccination if they were vaccinated 5 or more yr previously and were younger than 65 yr at the time of primary vaccination.

[9]Hepatitis A vaccination

Medical indications: Persons with chronic liver disease and persons who receive clotting factor concentrates.

Behavioral indications: Men who have sex with men and persons who use illegal drugs.

Occupational indications: Persons working with hepatitis A virus (HAV)–infected primates or with HAV in a research laboratory setting.

Other indications: Persons traveling to or working in countries that have high or intermediate endemicity of hepatitis A (a list of countries is available at wwwn.cdc.gov/travel/contentdiseases.aspx) and any person seeking protection from HAV infection.

Single-antigen vaccine formulations should be administered in a 2-dose schedule at either 0 and 6-12 mo (Havrix) or 0 and 6-18 mo (Vaqta). If the combined hepatitis A and hepatitis B vaccine (Twinrix) is used, administer 3 doses at 0, 1, and 6 mo; alternatively, a 4-dose schedule, administered on days 0, 7, and 21 to 30 followed by a booster dose at mo 12 may be used.

[10]Hepatitis B vaccination

Medical indications: Persons with end-stage renal disease, including patients receiving hemodialysis; persons with HIV infection; and persons with chronic liver disease.

Occupational indications: Health care personnel and public-safety workers who are exposed to blood or other potentially infectious body fluids.

Behavioral indications: Sexually active persons who are not in a long-term, mutually monogamous relationship (e.g., persons with more than 1 sex partner during the previous 6 mo); persons seeking evaluation or treatment for a sexually transmitted disease (STD); current or recent injection-drug users; and men who have sex with men.

Other indications: Household contacts and sex partners of persons with chronic hepatitis B virus (HBV) infection; clients and staff members of institutions for persons with developmental disabilities; international travelers to countries with high or intermediate prevalence of chronic HBV infection (a list of countries is available at wwwn.cdc.gov/travel/contentdiseases.aspx); and any adult seeking protection from HBV infection.

Hepatitis B vaccination is recommended for all adults in the following settings: STD treatment facilities, HIV testing and treatment facilities, facilities providing drug-abuse treatment and prevention services, health care settings targeting services to injection-drug users or men who have sex with men, correctional facilities, end-stage renal disease programs and facilities for chronic hemodialysis patients, and institutions and nonresidential day care facilities for persons with developmental disabilities.

If the combined hepatitis A and hepatitis B vaccine (Twinrix) is used, administer 3 doses at 0, 1, and 6 mo; alternatively, a 4-dose schedule, administered on days 0, 7, and 21 to 30 followed by a booster dose at mo 12 may be used.

Special formulation indications: For adult patients receiving hemodialysis or with other immunocompromising conditions, 1 dose of 40 μg/ml (Recombivax HB) administered on a 3-dose schedule or 2 doses of 20 μg/mL (Engerix-B) administered simultaneously on a 4-dose schedule at 0, 1, 2, and 6 mo.

[11]Meningococcal vaccination

Medical indications: Adults with anatomic or functional asplenia or terminal complement component deficiencies.

Other indications: First-yr college students living in dormitories; microbiologists who are routinely exposed to isolates of Neisseria meningitidis; military recruits; and persons who travel to or live in countries in which meningococcal disease is hyperendemic or epidemic (e.g., the "meningitis belt" of sub-Saharan Africa during the dry season [December-June]), particularly if their contact with local populations will be prolonged. Vaccination is required by the government of Saudi Arabia for all travelers to Mecca during the annual Hajj.

Meningococcal conjugate vaccine (MCV) is preferred for adults with any of the preceding indications who are aged 55 years or younger, although meningococcal polysaccharide vaccine (MPSV) is an acceptable alternative. Revaccination with MCV after 5 years might be indicated for adults previously vaccinated with MPSV who remain at increased risk for infection (e.g., persons residing in areas in which disease is epidemic).

[12]Selected conditions for which Haemophilus influenzae type b (Hib) vaccine may be used

Hib vaccine generally is not recommended for persons aged 5 years and older. No efficacy data are available on which to base a recommendation concerning use of Hib vaccine for older children and adults. However, studies suggest good immunogenicity in patients who have sickle cell disease, leukemia, or HIV infection or who have had a splenectomy; administering 1 dose of vaccine to these patients is not contraindicated.

[13]Immunocompromising conditions

Inactivated vaccines generally are acceptable (e.g., pneumococcal, meningococcal, and influenza [trivalent inactive influenza vaccine]) and live vaccines generally are avoided in persons with immune deficiencies or immuno-compromising conditions. Information on specific conditions is available at http://www.cdc.gov/vaccines/pubs/acip-list.htm.

TABLE 5-20 Immunization and Pregnancy

Vaccine	Before Pregnancy	During Pregnancy	After Pregnancy	Type of Vaccine	Route
Hepatitis A	If at high risk for disease	If at high risk for disease	If at high risk for disease	Inactivated	IM
Hepatitis B	Yes, if at risk	Yes, if at risk	Yes, if at risk	Inactivated	IM
Human papillomavirus (HPV)	Yes, if 9 to 26 years of age	No, under study	Yes, if 9 to 26 years of age	Inactivated	IM
Influenza TIV	Yes	Yes	Yes	Inactivated	IM
Influenza LAIV	Yes, if <50 years and healthy; avoid conception for 4 weeks	No	Yes, if <50 years and healthy; avoid conception for 4 weeks	Live	Nasal spray
MMR	Yes, avoid conception for 4 weeks	No	Yes, give immediately postpartum if susceptible to rubella	Live	SC
Meningococcal:	If indicated	If indicated	If indicated		
• Polysaccharide				Inactivated	SC
• Conjugate				Inactivated	IM
Pneumococcal polysaccharide	If indicated	If indicated	If indicated	Inactivated	IM or SC
Tetanus/diphtheria Td	Yes, Tdap preferred	If indicated	Yes, Tdap preferred	Toxoid	IM
Tdap, one dose only	Yes, preferred	If high risk of pertussis; otherwise, Td preferred	Yes, preferred	Toxoid/inactivated	IM
Varicella	Yes, avoid conception for 4 weeks	No	Yes, give immediately postpartum if susceptible	Live	SC

TABLE 5-21 Immunizing Agents and Immunization Schedules for Health Care Workers (HCWs)*

Generic Name	Primary Schedule and Booster(s)	Indications	Major Precautions and Contraindications	Special Considerations
Immunizing Agents Strongly Recommended for Health Care Workers				
Hepatitis B (HB) recombinant vaccine	Two doses IM 4 wk apart; third dose 5 mo after second; booster doses not necessary	**Preexposure:** HCWs at risk for exposure to blood or body fluids	Based on limited data no risk of adverse effects to developing fetuses is apparent. Pregnancy should *not* be considered a contraindication to vaccination of women. Previous anaphylactic reaction to common baker's yeast is a contraindication to vaccination.	The vaccine produces neither therapeutic nor adverse effects on HB-infected persons. Prevaccination serologic screening is not indicated for persons being vaccinated because of occupational risk. HCWs who have contact with patients or blood should be tested 1-2 mo after vaccination to determine serologic response.
Hepatitis B immune globulin (HBIG)	0.06 ml/kg IM as soon as possible after exposure. A second dose of HBIG should be administered 1 mo later if the HB vaccine series has not been started.	**Postexposure prophylaxis:** For persons exposed to blood or body fluids containing HBsAg and who are not immune to HBV infection—0.06 ml/kg IM as soon as possible (but no later than 7 days after exposure)		
Influenza vaccine (inactivated whole-virus and split-virus vaccines)	Annual vaccination with current vaccine Administered IM	HCWs who have contact with patients at high risk for influenza or its complications; HCWs who work in long-term care facilities; HCWs with high-risk medical conditions or who are aged ≥65 yr	History of anaphylactic hypersensitivity to egg ingestion	No evidence exists of risk to mother or fetus when the vaccine is administered to a pregnant woman with an underlying high-risk condition. Influenza vaccination is recommended during second and third trimesters of pregnancy because of increased risk for hospitalization.
Measles live-virus vaccine	One dose SC; second dose at least 1 mo later	HCWs† born during or after 1957 who do not have documentation of having received two doses of live vaccine on or after the first birthday **or** a history of physician-diagnosed measles or serologic evidence of immunity. Vaccination should be considered for all HCWs who lack proof of immunity, including those born before 1957.	Pregnancy; immunocompromised persons,‡ including HIV-infected persons who have evidence of severe immunosuppression; anaphylaxis after gelatin ingestion or administration of neomycin; recent administration of immune globulin.	MMR is the vaccine of choice if recipients are likely to be susceptible to rubella and/or mumps as well as measles. Persons vaccinated between 1963 and 1967 with a killed measles vaccine alone, killed vaccine followed by live vaccine, or with a vaccine of unknown type should be revaccinated with two doses of live measles virus vaccine.
Mumps live-virus vaccine	One dose SC; second dose at least 1 mo later	HCWs† believed to be susceptible can be vaccinated. Adults born before 1957 can be considered immune.	Pregnancy; immunocompromised persons,‡ history of anaphylactic reaction after gelatin ingestion or administration of neomycin	MMR is the vaccine of choice if recipients are likely to be susceptible to measles and rubella, as well as mumps.
Hepatitis A virus (HAV) vaccine	Two doses of vaccine either 6-12 mo apart (HAVRIX), or 6 mo apart (VAQTA)	Not routinely indicated for HCWs in the United States. Persons who work with HAV-infected primates or with HAV in a research laboratory setting should be vaccinated.	History of anaphylactic hypersensitivity to alum or, for HAVRIX, the preservative 2-phenoxyethanol. The safety of the vaccine in pregnant women has not been determined; the risk associated with vaccination should be weighed against the risk for hepatitis A in women who may be at high risk for exposure to HAV.	
Meningococcal polysaccharide vaccine (tetravalent A, C, W135, and Y)	One dose in volume and by route specified by manufacturer; need for boosters unknown	Not routinely indicated for HCWs in the United States.	The safety of the vaccine in pregnant women has not been evaluated; it should not be administered during pregnancy unless the risk for infection is high.	

Modified from *MMWR* 46(RR-18), 1998.

HBsAg, Hepatitis B surface antigen; *HBV,* hepatitis B virus; *HIV,* human immunodeficiency virus; *IM,* intramuscularly; *MMR,* measles, mumps, rubella vaccine; *SC,* subcutaneously; *TB,* tuberculosis.

*Persons who provide health care to patients or work in institutions that provide patient care (e.g., physicians, nurses, emergency medical personnel, dental professionals and students, medical and nursing students, laboratory technicians, hospital volunteers, and administrative and support staff in health care institutions).

†All HCWs (i.e., medical or nonmedical, paid or volunteer, full time or part time, student or nonstudent, with or without patient-care responsibilities) who work in health care institutions (e.g., inpatient and outpatient, public and private) should be immune to measles, rubella, and varicella.

‡Persons immunocompromised because of immune deficiency diseases, HIV infection, leukemia, lymphoma or generalized malignancy, or immunosuppressed as a result of therapy with corticosteroids, alkylating drugs, antimetabolites, or radiation.

Continued on following page

TABLE 5-21 Immunizing Agents and Immunization Schedules for Health Care Workers (HCWs)—cont'd

Generic Name	Primary Schedule and Booster(s)	Indications	Major Precautions and Contraindications	Special Considerations
Typhoid vaccine, IM, SC, and oral	IM vaccine: One 0.5-ml/dose, booster 0.5 ml every 2 yr SC vaccine: Two 0.5-ml doses, ≥4 wk apart, booster 0.5 ml SC or 0.1 ID every 3 yr if exposure continues Oral vaccine: Four doses on alternate days. The manufacturer recommends revaccination with the entire 4-dose series every 5 yr	Workers in microbiology laboratories who frequently work with *Salmonella typhi*	Severe local or systemic reaction to a previous dose. Ty21a (oral) vaccine should not be administered to immunocompromised persons† or to persons receiving antimicrobial agents.	Vaccination should not be considered an alternative to the use of proper procedures when handling specimens and cultures in the laboratory.
Vaccinia vaccine (smallpox)	One dose administered with a bifurcated needle; boosters administered every 10 yr	Laboratory workers who directly handle cultures with vaccinia, recombinant vaccinia viruses, or orthopox viruses that infect human beings	The vaccine is contraindicated in pregnancy, in persons with eczema or a history of eczema, and in immunocompromised persons† and their household contacts.	Vaccination may be considered for HCWs who have direct contact with contaminated dressings or other infectious material from volunteers in clinical studies involving recombinant vaccinia virus.
Other Vaccine-Preventable Diseases				
Tetanus and diphtheria (toxoids [Td])	Two IM doses 4 wk apart; third dose 6-12 mo after second dose; booster every 10 yr	All adults	Except in the first trimester, pregnancy is not a precaution. History of a neurologic reaction or immediate hypersensitivity reaction after a previous dose. History of severe local (arthus-type) reaction after a previous dose. Such persons should not receive further routine or emergency doses of Td for 10 yr.	Tetanus prophylaxis in wound management‡
Pneumococcal polysaccharide vaccine (23 valent)	One dose, 0.5 ml, IM or SC; revaccination recommended for those at highest risk ≥5 yr after the first dose	Adults who are at increased risk of pneumococcal disease and its complications because of underlying health conditions; older adults, especially those age ≥65 who are healthy	The safety of vaccine in pregnant women has not been evaluated; it should not be administered during pregnancy unless the risk for infection is high. Previous recipients of any type of pneumococcal polysaccharide vaccine who are at highest risk for fatal infection or antibody loss may be revaccinated ≥5 yr after the first dose.	
Rubella live-virus vaccine	One dose SC; second dose at least 1 mo later	Indicated for HCWs,† both men and women, who do not have documentation of having received live vaccine on or after their first birthday **or** laboratory evidence of immunity. Adults born before 1957, **except women who can become pregnant,** can be considered immune.	Pregnancy; immunocompromised persons†; history of anaphylactic reaction after administration of neomycin	The risk for rubella vaccine–associated malformations in the offspring of women pregnant when vaccinated or who become pregnant within 3 mo after vaccination is negligible. Such women should be counseled regarding the theoretic basis of concern for the fetus. MMR is the vaccine of choice if recipients are likely to be susceptible to measles or mumps as well as rubella.
Varicella zoster live-virus vaccine	Two 0.5-ml doses SC 4-8 wk apart if ≥13 yr	Indicated for HCWs† who do not have either a reliable history of varicella or serologic evidence of immunity	Pregnancy, immunocompromised persons,‡ history of anaphylactic reaction after receipt of neomycin or gelatin. Avoid salicylate use for 6 wk after vaccination.	Vaccine is available from the manufacturer for certain patients with acute lymphocytic leukemia in remission. Because 71%-93% of persons without a history of varicella are immune, serologic testing before vaccination is likely to be cost effective.

TABLE 5-21 Immunizing Agents and Immunization Schedules for Health Care Workers (HCWs)—cont'd

Generic Name	Primary Schedule and Booster(s)	Indications	Major Precautions and Contraindications	Special Considerations
Varicella-zoster immune globulin (VZIG)	Persons <50 kg: 125 μ/10 kg IM; persons ≥50 kg: 625 μ[§]	Persons known or likely to be susceptible (particularly those at high risk for complications, e.g., pregnant women) who have close and prolonged exposure to a contact case or to an infectious hospital staff worker or patient		Serologic testing may help in assessing whether to administer VZIG. If use of VZIG prevents varicella disease, patient should be vaccinated subsequently.
BCG Vaccination				
Bacille Calmette-Guérin (BCG) vaccine (TB)	One percutaneous dose of 0.3 ml; no booster dose recommended	Should be considered only for HCWs in areas where multidrug TB is prevalent, a strong likelihood of infection exists, and where comprehensive infection control precautions have failed to prevent TB transmission to HCWs	Should not be administered to immunocompromised persons,[‡] pregnant women	In the United States TB-control efforts are directed toward early identification, treatment of cases, and preventive therapy with isoniazid.
Other Immunobiologics that Are or May Be Indicated for HCWs				
Immune globulin (hepatitis A)	**Postexposure**—One IM dose of 0.02 ml/kg administered ≤2 wk after exposure	Indicated for HCWs exposed to feces of infectious patients	Contraindicated in persons with IgA deficiency; do not administer within 2 wk after MMR vaccine or 3 wk after varicella vaccine. Delay administration of MMR vaccine for ≥3 mo and varicella vaccine ≥5 mo after administration of immune globulin	Administer in large muscle mass (deltoid, gluteal).

Modified from *MMWR* 46(RR-18), 1998.

HBsAg, Hepatitis B surface antigen; *HBV,* hepatitis B virus; *HIV,* human immunodeficiency virus; *IM,* intramuscular; *MMR,* measles, mumps, rubella vaccine; *SC,* subcutaneous; *TB,* tuberculosis.

*Persons who provide health care to patients or work in institutions that provide patient care (e.g., physicians, nurses, emergency medical personnel, dental professionals and students, medical and nursing students, laboratory technicians, hospital volunteers, and administrative and support staff in health care institutions).

†All HCWs (i.e., medical or nonmedical, paid or volunteer, full time or part time, student or nonstudent, with or without patient-care responsibilities) who work in health care institutions (e.g., inpatient and outpatient, public and private) should be immune to measles, rubella, and varicella.

‡Persons immunocompromised because of immune deficiency diseases, HIV infection, leukemia, lymphoma or generalized malignancy, or immunosuppressed as a result of therapy with corticosteroids, alkylating drugs, antimetabolites, or radiation.

§Some experts recommend 125 μ/10 kg regardless of total body weight.

TABLE 5-22 Recommendations for Persons with Medical Conditions Requiring Special Vaccination Considerations

Condition	Td	MMR	Varicella	HBV	HAV	Pneumovax[a]	Influenza[b]	HbCV	Meningococcal	IPV	Other Live Vaccines[c]	Other Killed Vaccines[d]

Modified and updated from *MMWR* 42(RR-4):16, 1993.

Cons, Consider vaccination; *Contr,* contraindicated; *HbCV, Haemophilus influenzae* conjugate vaccine; *HBV,* hepatitis B virus; *IPV,* inactivated poliomyelitis vaccine; *MMR,* measles-mumps-rubella; *Rec,* recommended; *Rou,* routine as outlined for all adults.

[a]Pneumovax should be repeated in 5 yr for patients in whom vaccine is recommended. Asthma without chronic obstructive pulmonary disease is not an indication for the vaccine.

[b]Influenza vaccine should also be given to caregivers and household members.

[c]Includes bacille Calmette-Guérin, vaccinia, oral typhoid, yellow fever (if exposure cannot be avoided, persons with HIV can be given yellow fever vaccine; see text).

[d]Includes rabies (check postvaccination titers in HIV or severely immunocompromised persons), Lyme disease, inactivated typhoid, cholera, plague, and anthrax.

[e]For asymptomatic, nonseverely immunocompromised persons with HIV, MMR can be used; it is contraindicated in severely immunocompromised persons. MMR can be considered in symptomatic HIV patients without severe immunocompromise.

[f]Varicella can be given to household members and caregivers, but if varicella-like rash develops after vaccination, contact should be avoided.

[g]Recommended for persons with severe chronic renal failure approaching or already receiving dialysis, and higher doses should be given. Antibody titers should be measured after vaccination in these patients and in those with HIV or severe immunocompromise (who may require higher doses) to ensure adequate response. Yearly titers should be measured in dialysis patients.

[h]Severe immunocompromise can result from congenital immunodeficiency, leukemia, lymphoma, malignancy, organ transplant, chemotherapy, radiation therapy, or high-dose corticosteroids.

[i]Only for persons with Hodgkin's disease.

[j]Give at least 2 wk in advance of elective splenectomy.

TABLE 5-23 Vaccinations for International Travel

Disease*	Areas Affected†	Prophylaxis Recommended	Ideal Time between Last Vaccine Dose and Travel
Tetanus	All	All travelers; vaccine series/booster	Probably 30 days for series Anamnestic response to booster
Measles	All	If born after 1956; ensure immunity by antibody titer, diagnosed measles, or two doses of vaccine	As MMR, 7-14 days
Rubella	All	If born after 1956 and any female of childbearing age; rubella titer or one dose of vaccine	As MMR, 7-14 days
Mumps	All	If born after 1956; ensure immunity by antibody titer, diagnosed mumps, or one dose of vaccine	As MMR, 7-14 days
Varicella	All	All travelers; antibody titer, reported illness, or vaccine series	7-14 days
Hepatitis B	5%-20% of population are carriers in Africa, Middle East except Israel, all Southeast Asia, Amazon basin, Haiti, and Dominican Republic; 1%-5% of population are carriers in south-central and southwest Asia, Israel, Japan, Americas, Russia, and eastern and southern Europe	Travelers for more than 6 mo in close contact with population or for less time but with high-risk activities (close household contact, seeking dental or medical care, sex); vaccine series	Probably 30 days
Hepatitis A	Developing countries	Travelers to rural areas; eating and drinking in settings of poor sanitation; vaccine or pooled immune globulin	Vaccine, 30 days Pooled IG, 2 days
Influenza	Tropics throughout the year; southern hemisphere from April to September	Travelers for whom vaccine is otherwise indicated; give current vaccine and revaccinate in fall as usual	7-14 days
Meningococcus*	Sub-Saharan Africa "belt" (Senegal to Ethiopia) from December to June; required for pilgrims to Saudi Arabia during Hajj; epidemics reported in other African nations, India, Nepal, and Mongolia	All travelers; vaccine	7-10 days
Rabies	Endemic dog rabies exists in Mexico, El Salvador, Guatemala, Peru, Colombia, Ecuador, India, Nepal, Philippines, Sri Lanka, Thailand, and Vietnam	Travelers staying for more than 30 days or at high risk of exposure to domestic or wild animals; vaccine series/booster	7-14 days
Poliomyelitis	Developing countries not in western hemisphere; at risk all year in tropics; in temperate zones, incidence increases in summer and fall	All travelers; vaccine series/booster	Parenteral vaccine series, 28 day (see text)
Typhoid fever	Many countries in Asia, Africa, Central America, and South America	Travelers with prolonged stay in rural areas with poor sanitation; vaccine series/booster	Oral vaccine, 7 days Parenteral vaccine, probably 14 days
Yellow fever*	North and central South America, forest-savannah zones of Africa; some countries in Africa, Asia, and Middle East require travelers from endemic areas to be vaccinated	All travelers; vaccine/booster at approved yellow fever vaccination center.	10 days
Japanese encephalitis	Seasonally in most areas of Asia, Indian subcontinent, and western Pacific islands; in temperate zones, incidence increases in summer and early fall; in tropics, year-round incidence	Travelers staying for more than 30 days in high-risk rural areas; staying outdoors during transmission season; vaccine series	10 days
Cholera*	Certain undeveloped countries	If required by local authorities, one dose usually suffices; primary series only for those living in high-risk areas under poor sanitary conditions or those with compromised gastric defense mechanisms (achlorhydria, antacid therapy, previous ulcer surgery); booster every 6 mo	Probably 30 days
Plague	Africa, Asia, and Americas in rural mountainous or upland areas	Travelers whose research or field activities bring them in contact with rodents; vaccine series/booster; consider taking tetracycline (500 mg four times a day) for chemoprophylaxis (inferred from clinical experience in treating plague)	Probably 30 days

From Noble J: *Primary care medicine,* ed 3, St Louis, 2001, Mosby.

MMR, Measles-mumps-rubella.

*Only yellow fever vaccine is required for entry by any country; cholera vaccine may be required by some local authorities. Meningococcus vaccine is required for pilgrims to Mecca, in Saudia Arabia, during Hajj. However, it is important to follow Centers for Disease Control and Prevention (CDC) recommendations for all vaccines to prevent disease. If a required vaccine is contraindicated or withheld for any reason, attempts should be made to obtain a waiver from the country's consulate or embassy.

†Because areas affected can change, and for more specific details, consult the CDC's traveler's hotline.

Recommendations and Implementation Strategies for Hepatitis B Vaccination of Adults

BOX 5-1 Adults Recommended to Receive Hepatitis B Vaccination

Persons at Risk for Infection by Sexual Exposure
- Sex partners of persons who are HBsAg positive
- Sexually active persons who are not in a long-term, mutually monogamous relationship (e.g., persons who have had more than one sex partner during the previous 6 months)
- Persons seeking evaluation or treatment for a sexually transmitted disease
- Men who have sex with men

Persons at Risk for Infection by Percutaneous or Mucosal Exposure to Blood
- Current or recent users of injection drugs
- Household contacts of persons who are HBsAg positive
- Residents and staff of facilities for developmentally disabled persons
- Health care and public safety workers with reasonably anticipated risk for exposure to blood or blood-contaminated body fluids
- Persons with end-stage renal disease, including predialysis, hemodialysis, peritoneal dialysis, and home dialysis patients

Others
- International travelers to regions with high or intermediate levels (HBsAg prevalence of ≥2%) of endemic HBV infection
- Persons with chronic liver disease
- Persons with HIV infection
- All other persons seeking protection from HBV infection

From CDC: A comprehensive immunization strategy to eliminate transmission of hepatitis B virus infection in the United States: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-16):15, 2006.

TABLE 5-26 Guidelines for Postexposure Prophylaxis* of Persons with Nonoccupational Exposures† to Blood or Body Fluids That Contain Blood by Exposure Type and Vaccination Status

	TREATMENT	
Exposure	**Unvaccinated Person‡**	**Previously Vaccinated Person§**
HBsAg-Positive Source		
Percutaneous (e.g., bite or needlestick) or mucosal exposure to HBsAg-positive blood or body fluids	Administer hepatitis B vaccine series and hepatitis B immune globulin (HBIG)	Administer hepatitis B vaccine booster dose
Sex or needle-sharing contact with a person who is HBsAg positive	Administer hepatitis B vaccine series and HBIG	Administer hepatitis B vaccine booster dose
Victim of sexual assault/abuse by a perpetrator who is HBsAg positive	Administer hepatitis B vaccine series and HBIG	Administer hepatitis B vaccine booster dose
Source with Unknown HBsAg Status		
Victim of sexual assault/abuse by a perpetrator with unknown HBsAg status	Administer hepatitis B vaccine series	No treatment
Percutaneous (e.g., bite or needlestick) or mucosal exposure to potentially infectious blood or body fluids from a source with unknown HBsAg status	Administer hepatitis B vaccine series	No treatment
Sexual or needle-sharing contact with person with unknown HBsAg status	Administer hepatitis B vaccine series	No treatment

From Centers for Disease Control and Prevention: A comprehensive immunization strategy to eliminate transmission of hepatitis B virus infection in the United States: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-16):30, 2006.

HBsAg, Hepatitis B surface antigen.

*When indicated, immunoprophylaxis should be initiated as soon as possible, preferably within 24 hours. Studies are limited on the maximum interval after exposure during which postexposure prophylaxis is effective, but the interval is unlikely to exceed 7 days for percutaneous exposures or 14 days for sexual exposures. The hepatitis B vaccine series should be completed.

†These guidelines apply to nonoccupational exposures. Guidelines for management of occupational exposures have been published separately and also can be used for management of nonoccupational exposures if feasible.

‡A person who is in the process of being vaccinated but has not completed the vaccine series should complete the series and receive treatment as indicated.

§A person who has written documentation of a complete hepatitis B vaccine series and did not receive postvaccination testing.

TABLE 5-27 Typical Interpretation of Serologic Test Results for Hepatitis B Virus Infection

SEROLOGIC MARKER				
HBsAg	**Total Anti-HBc**	**IgM Anti-HBc**	**Anti-HBs**	**Interpretation**
−*	−	−	−	Never infected
+†‡	−	−	−	Early acute infection; transient (up to 18 days) after vaccination
+	+	+	−	Acute infection
−	+	+	+ or −	Acute resolving infection
−	+	−	+	Recovered from past infection and immune
+	+	−	−	Chronic infection
−	+	−	−	False-positive (i.e., susceptible), past infection, "low-level" chronic infection,§ or passive transfer of anti-HBc to infant born to mother who is HBsAg positive
−	−	−	+	Immune if concentration is >10 mIU/ml after vaccine series completion‖; passive transfer after hepatitis B immune globulin administration

From Centers for Disease Control and Prevention: A comprehensive immunization strategy to eliminate transmission of hepatitis B virus infection in the United States: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-16):4, 2006.

HBc, Antibody to hepatitis B core antigen; *HBs,* antibody to HBsAg; *HBsAg,* hepatitis B surface antigen; *Ig,* immunoglobulin.

*Negative test result.

†Positive test result.

‡To ensure that an HBsAg-positive test result is not a false-positive, samples with reactive HBsAg results should be tested with a licensed neutralizing confirmatory test if recommended in the manufacturer's package insert.

§Persons positive only for anti-HBc are unlikely to be infectious except under unusual circumstances in which they are the source for direct percutaneous exposure of susceptible recipients to large quantities of virus (e.g., blood transfusion or organ transplant).

‖Milliinternational units per milliliter.

Hepatitis A Prophylaxis

TABLE 5-28 Recommended Dosages of Hepatitis A Immune Globulin

Setting	Duration of Coverage	Dose
Preexposure prophylaxis	Short term (<3 mo)	0.02 ml/kg
	Long term (3-5 mo)*	0.06 ml/kg
Postexposure prophylaxis	—	0.02 ml/kg

Modified from Centers for Disease Control and Prevention: Prevention of hepatitis A through active or passive immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-07):9, 2006.

NOTE: Immune globulin should be administered intramuscularly into the deltoid or gluteal muscle in children younger than 24 mo; it may be administered in the anterolateral thigh muscle.

*Repeat every 5 mo if continued exposure to hepatitis A virus occurs.

TABLE 5-29 Licensed Dosages of Hepatitis A Vaccines

Vaccine	Patient's Age	Dose	Volume (ml)	Number of Doses	Schedule (mo)*
Hepatitis A vaccine, inactivated (Havrix)	12 mo to 18 yr	720 EL.U.	0.5	2	0, 6-12
	≥19 yr	1440 EL.U.	1.0	2	0, 6-12
Hepatitis A vaccine, inactivated (Vaqta)	12 mo to 18 yr	25 U	0.5	2	0, 6-18
	≥19 yr	50 U	1.0	2	0, 6-18
Combined hepatitis A and hepatitis B vaccine (Twinrix)	≥18 yr	720 EL.U. of hepatitis A antigen and 20 mcg of hepatitis B surface antigen protein	1.0	3	0, 1, and 6

Modified from Centers for Disease Control and Prevention: Prevention of hepatitis A through active or passive immunization: recommendations of the Advisory Committee on Immunization Practices (ACIP), *MMWR* 55(RR-07):10, 2006.

*Zero represents the timing of the initial dose; subsequent numbers represent months after the initial dose.

Influenza Treatment and Prophylaxis

BOX 5-3 Summary of Seasonal Influenza Vaccination Recommendations

Children
All children aged 6 months-18 years should be vaccinated annually.

Children and adolescents at higher risk for influenza complications should continue to be a focus for vaccination efforts as providers and programs transition to routinely vaccinating all children and adolescents, including those who:

- are aged 6 months-4 years (59 months)
- have chronic pulmonary (including asthma), cardiovascular (except hypertension), renal, hepatic, cognitive, neurologic/neuromuscular, hematologic, or metabolic disorders (including diabetes mellitus)
- are immunosuppressed (including immunosuppression caused by medications or by human immunodeficiency virus)
- are receiving long-term aspirin therapy and therefore might be at risk for experiencing Reye's syndrome after influenza virus infection
- are residents of long-term care facilities
- will be pregnant during the influenza season

Note: Children aged <6 months cannot receive influenza vaccination. Household and other close contacts (e.g., day-care providers) of children aged <6 months, including older children and adolescents, should be vaccinated.

Adults
Annual vaccination against influenza is recommended for any adult who wants to reduce the risk of becoming ill with influenza or of transmitting it to others. Vaccination is recommended for all adults without contraindications in the following groups, because these persons either are at higher risk for influenza complications, or are close contacts of the persons at higher risk:

- persons aged ≥50 years
- women who will be pregnant during the influenza season
- persons who have chronic pulmonary (including asthma), cardiovascular (except hypertension), renal, hepatic, cognitive, neurologic/neuromuscular, hematologic, or metabolic disorders (including diabetes mellitus)
- persons who have immunosuppression (including immunosuppression caused by medications or by human immunodeficiency virus)
- residents of nursing homes and other long-term care facilities
- health-care personnel
- household contacts and caregivers of children aged <5 years and adults aged ≥50 years, with particular emphasis on vaccinating contacts of children aged <6 months
- household contacts and caregivers of persons with medical conditions that put them at higher risk for severe complications from influenza

Modified from *MMWR* 58:(RR-8), 2009.

RECOMMENDED VACCINES FOR DIFFERENT AGE GROUPS

When vaccinating children aged 6 to 35 months with TIV, health care providers should use TIV that has been licensed by the FDA for this age group (i.e., TIV manufactured by Sanofi Pasteur [FluZone]). TIV from Novartis (Fluvirin) is FDA approved in the United States for use among persons aged 4 years and older. TIV from GlaxoSmithKline (Fluarix and FluLaval) or CSL Biotherapies (Afluria) is labeled for use in persons aged 18 years and older because data to demonstrate efficacy among younger persons have not been provided to the FDA. LAIV from MedImmune (FluMist) is licensed for use by healthy, nonpregnant persons aged 2 to 49 years. A vaccine dose does not need to be repeated if inadvertently administered to a person who does not have an age indication for the vaccine formulation given. Expanded age and risk group indications for licensed vaccines are likely over the next several years, and vaccination providers should be alert to these changes. In addition, several new vaccine formulations are being evaluated in immunogenicity and efficacy trials; when licensed, these new products will increase the influenza vaccine supply and provide additional vaccine choices for practitioners and their patients.

INFLUENZA VACCINES AND USE OF INFLUENZA ANTIVIRAL MEDICATIONS

Administration of TIV and influenza antivirals during the same medical visit is acceptable. The effect on safety and effectiveness of LAIV coadministration with influenza antiviral medications has not been studied. However, because influenza antivirals reduce replication of influenza viruses, LAIV should not be administered until 48 hours after cessation of influenza antiviral therapy, and influenza antiviral medications should not be administered for 2 weeks after receipt of LAIV. Persons receiving antivirals within the period 2 days before to 14 days after vaccination with LAIV should be revaccinated at a later date.

PERSONS WHO SHOULD NOT BE VACCINATED WITH TIV

TIV should not be administered to persons known to have anaphylactic hypersensitivity to eggs or other components of the influenza vaccine. Prophylactic use of antiviral agents is an option for preventing influenza among such persons. Information about vaccine components is located in package inserts from each manufacturer. Persons with moderate to severe acute febrile illness usually should not be vaccinated until their symptoms have abated. However, minor illnesses with or without fever do not contraindicate use of influenza vaccine. Guillaine-Barré syndrome within 6 weeks after a previous dose of TIV is considered a precaution for use of TIV.

CONSIDERATIONS WHEN USING LAIV

LAIV is an option for vaccination of healthy, nonpregnant persons aged 2 to 49 years, including health care providers and other close contacts of high-risk persons (except severely immunocompromised persons who require care in a protected environment). No preference is indicated for LAIV or TIV when considering vaccination of healthy, nonpregnant persons aged 2 to 49 years. Use of the term *healthy* in this recommendation refers to persons who do not have any of the underlying medical conditions that confer high risk for severe complications (see "Persons Who Should Not Be Vaccinated with LAIV"). However, during periods when inactivated vaccine is in short supply, use of LAIV is encouraged when feasible for eligible persons (including health care providers) because use of LAIV by these persons might increase availability of TIV for persons in groups targeted for vaccination but who cannot receive LAIV. Possible advantages of LAIV include its potential to induce a broad mucosal and systemic immune response in children, its ease of administration, and possibly increased acceptability of an intranasal rather than intramuscular route of administration.

If the vaccine recipient sneezes after administration, the dose should not be repeated. However, if nasal congestion is present that might impede delivery of the vaccine to the nasopharyngeal mucosa, deferral of administration should be considered until resolution of the illness, or TIV should be administered instead. No data exist about concomitant use of nasal corticosteroids or other intranasal medications.

Although FDA licensure of LAIV excludes children aged 2 to 4 years with a history of asthma or recurrent wheezing, the precise risk, if any, of wheezing caused by LAIV among these children is unknown because experience with LAIV among these young children is limited. Young children might not have a history of recurrent wheezing if their exposure to respiratory viruses has been limited because of their age. Certain children might have a history of wheezing with respiratory illnesses but have not had asthma diagnosed. The following screening recommendations should be used to assist persons who administer influenza vaccines in providing the appropriate vaccine for children aged 2 to 4 years.

Clinicians and vaccination programs should screen for possible reactive airways diseases when considering use of LAIV for children aged 2 to 4 years and should avoid use of this vaccine in children with asthma or a recent wheezing episode. Health care providers should consult the medical record, when available, to identify children aged 2 to 4 years with asthma or recurrent wheezing that might indicate asthma. In addition, to identify children who might be at greater risk for asthma and possibly at increased risk for wheezing after receiving LAIV, parents or caregivers of children aged 2 to 4 years should be asked, "In the past 12 months, has a health care provider ever told you that your child had wheezing or asthma?" Children whose parents or caregivers answer "yes" to this question and children who have asthma or who had a wheezing episode noted in the medical record during the preceding 12 months should not receive LAIV. TIV is available for use in children with asthma or possible reactive airways diseases.

LAIV can be administered to persons with minor acute illnesses (e.g., diarrhea or mild upper respiratory tract infection with or without fever). However, if nasal congestion is present that might impede delivery of the vaccine to the nasopharyngeal mucosa, deferral of administration should be considered until resolution of the illness.

PERSONS WHO SHOULD NOT BE VACCINATED WITH LAIV

The effectiveness or safety of LAIV is not known for the following groups, who should not be vaccinated with LAIV:

- Persons with a history of hypersensitivity, including anaphylaxis, to any of the components of LAIV or eggs
- Persons younger than 2 years or aged 50 years or older
- Persons with any of the underlying medical conditions that serve as an indication for routine influenza vaccination, including asthma, reactive airways disease, or other chronic disorders of the pulmonary or cardiovascular systems; other underlying medical conditions, including metabolic diseases such as diabetes, renal dysfunction, and hemoglobinopathies; or known or suspected immunodeficiency diseases or immunosuppressed states
- Children aged 2 to 4 years whose parents or caregivers report that a health care provider has told them during the preceding 12 months that their child had wheezing or asthma, or whose medical record indicates a wheezing episode has occurred during the preceding 12 months
- Children or adolescents receiving aspirin or other salicylates (because of the association of Reye syndrome with wild-type influenza virus infection)
- Persons with a history of Guillaine-Barré syndrome after influenza vaccination
- Pregnant women

Concurrent Administration of Influenza Vaccine with Other Vaccines

Use of LAIV concurrently with measles, mumps, rubella (MMR) alone, and MMR and varicella vaccine among children aged 12 to 15 months has been studied, and no interference with immunogenicity to antigens in any of the vaccines was observed. Among adults aged 50 years or older, the safety and immunogenicity of zoster vaccine and TIV were similar whether administered simultaneously or spaced 4 weeks apart. In the absence of specific data indicating interference, following ACIP's general recommendations for vaccination is prudent. Inactivated vaccines do not interfere with the immune response to other inactivated vaccines or to live vaccines. Inactivated or live vaccines can be administered simultaneously with LAIV. However, after administration of a live vaccine, at least 4 weeks should pass before another live vaccine is administered.

TABLE 5-30 Live Attenuated Influenza Vaccine (LAIV) Compared with Inactivated Influenza Vaccine (TIV) for Seasonal Influenza, United States Formulations

Factor	LAIV	TIV
Route of administration	Intranasal spray	Intramuscular injection
Type of vaccine	Live virus	Noninfectious virus (i.e.,inactivated)
Number of included virus strains	3 (2 influenza A, 1 influenza B)	3 (2 influenza A, 1 influenza B)
Vaccine virus strains updated	Annually	Annually
Frequency of administration	Annually*	Annually*
Approved age	Persons aged 2-49 yr	Persons aged ≥6 mo
Interval between 2 doses recommended for children aged ≥6 mo to 8 yr who are receiving influenza vaccine for the first time	4 wk	4 wk
Can be administered to persons with medical risk factors for influenza-related complications†	No	Yes
Can be administered to children with asthma or children aged 2-4 yr with wheezing during the preceding year§	No	Yes
Can be administered to family members or close contacts of immunosuppressed persons not requiring a protected environment	Yes	Yes
Can be administered to family members or close contacts of immunosuppressed persons requiring a protected environment (e.g., hematopoietic stem cell transplant recipient)	No	Yes
Can be administered to family members or close contacts of persons at high risk but not severely immunosuppressed	Yes	Yes
Can be simultaneously administered with other vaccines	Yes¶	Yes**
If not simultaneously administered, can be administered within 4 wk of another live vaccine	Prudent to space 4 wk apart	Yes
If not simultaneously administered, can be administered within 4 wk of an inactivated vaccine	Yes	Yes

Modified from *MMWR* 56(RR-6), 2007.

LAIV, Live attenuated influenza vaccine; *TIV,* inactivated influenza vaccine.

*Children aged 6 months-8 years who have never received influenza vaccine before should receive 2 doses. Those who only receive 1 dose in their first year of vaccination should receive 2 doses in the following year, spaced 4 weeks apart.

†Persons at higher risk for complications of influenza infection because of underlying medical conditions should not receive LAIV. Persons at higher risk for complications of influenza infection because of underlying medical conditions include adults and children with chronic disorders of the pulmonary or cardiovascular systems; adults and children with chronic metabolic diseases (including diabetes mellitus), renal dysfunction, hemoglobinopathies, or immunosuppression; children and adolescents receiving long-term aspirin therapy (at risk for developing Reye's syndrome after wild-type influenza infection); persons who have any condition (e.g., cognitive dysfunction, spinal cord injuries, seizure disorders, or other neuromuscular disorders) that can compromise respiratory function or the handling of respiratory secretions or that can increase the risk for aspiration; pregnant women; and residents of nursing homes and other chronic-care facilities that house persons with chronic medical conditions.

§Clinicians and immunization programs should screen for possible reactive airways diseases when considering use of LAIV for children aged 2-4 years and should avoid use of this vaccine in children with asthma or a recent wheezing episode. Health care providers should consult the medical record, when available, to identify children aged 2-4 years with asthma or recurrent wheezing that might indicate asthma. In addition, to identify children who might be at greater risk for asthma and possibly at increased risk for wheezing after receiving LAIV, parents or caregivers of children aged 2-4 years should be asked: "In the past 12 months, has a health care provider ever told you that your child had wheezing or asthma?" Children whose parents or caregivers answer "yes" to this question and children who have asthma or who had a wheezing episode noted in the medical record during the preceding 12 months should not receive LAIV.

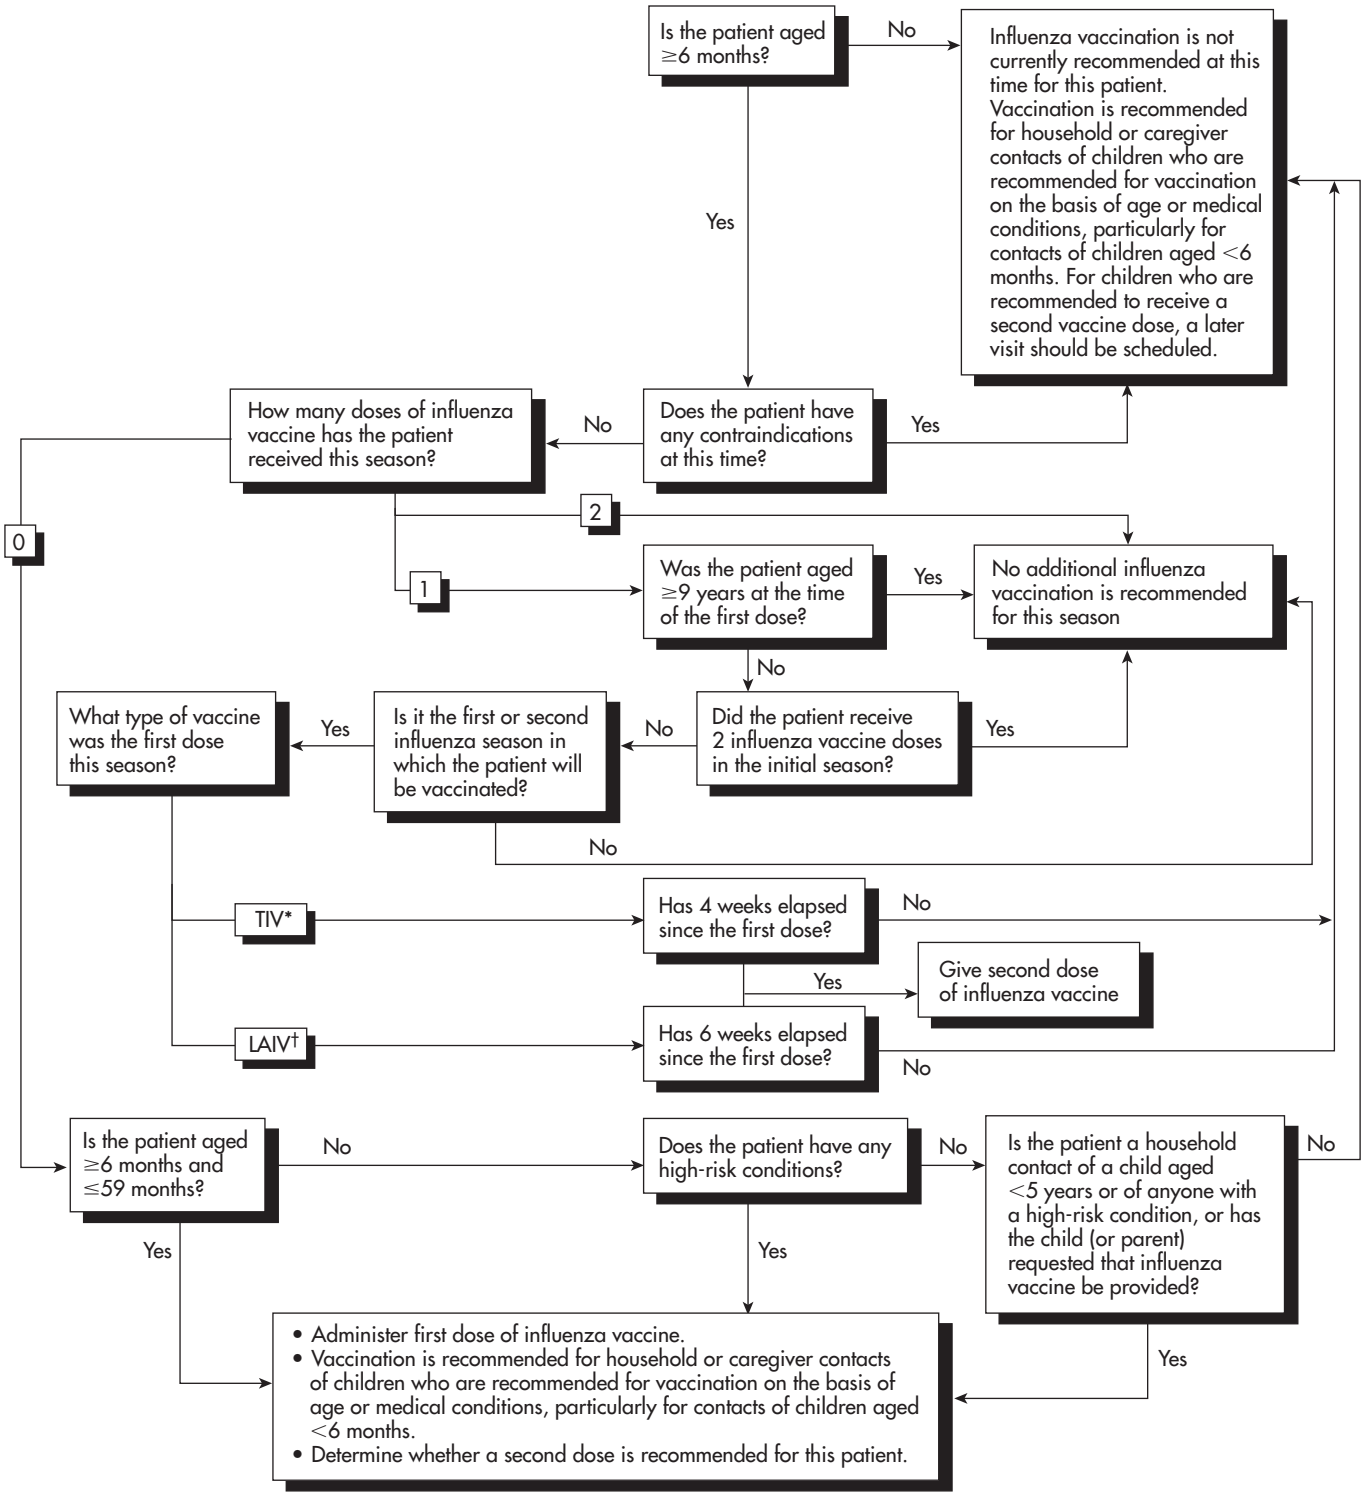
¶LAIV coadministration has been evaluated systematically only among children aged 12–15 months who received measles, mumps, and rubella vaccine or varicella vaccine.

**TIV coadministration has been evaluated systematically only among adults who received pneumococcal polysaccharide or zoster vaccine.

INDICATIONS FOR USE OF ANTIVIRALS

PERSONS FOR WHOM ANTIVIRAL TREATMENT SHOULD BE CONSIDERED

If possible, antiviral treatment should be started within 48 hours of influenza illness onset. The effectiveness of initiating antiviral treatment more than 48 hours after illness onset has not been established. Persons for whom antiviral treatment should be considered include:



- Persons hospitalized with laboratory-confirmed influenza (limited data suggest benefit even for persons whose antiviral treatment is initiated more than 48 hours after illness onset)
- Persons with laboratory-confirmed influenza pneumonia
- Persons with laboratory-confirmed influenza and bacterial coinfection
- Persons with laboratory-confirmed influenza infection who are at higher risk for influenza complications
- Persons presenting to medical care with laboratory-confirmed influenza within 48 hours of influenza illness onset who want to decrease the duration or severity of their symptoms and transmission of influenza to others at higher risk for complications

PERSONS FOR WHOM ANTIVIRAL CHEMOPROPHYLAXIS SHOULD BE CONSIDERED DURING PERIODS OF INCREASED INFLUENZA ACTIVITY IN THE COMMUNITY

- Persons at high risk during the 2 weeks after influenza vaccination (after the second dose for children younger than 9 years who have not previously been vaccinated) if influenza viruses are circulating in the community
- Persons at high risk for whom influenza vaccine is contraindicated
- Family members or health care providers who are unvaccinated and are likely to have ongoing, close exposure to persons at high risk or unvaccinated persons or infants younger than 6 months
- Persons and their family members and close contacts and health care workers when circulating strains of influenza virus in the community are not matched with vaccine strains
- Persons with immune deficiencies or those who might not respond to vaccination (e.g., persons infected with HIV or other immunosuppressed conditions or who are receiving immunosuppressive medications)
- Unvaccinated staff and persons during response to an outbreak in a closed institutional setting with residents at high risk (e.g., extended-care facilities)

Modified from *MMWR* 57(RR-7), 2008.

Note: Recommended antiviral medications (neuraminidase inhibitors) are not licensed for chemoprophylaxis of children younger than 1 year (oseltamivir) or younger than 5 years (zanamivir). Updates or supplements to these recommendations (e.g., expanded age or risk group indications for licensed vaccines) might be required. Health care providers should be alert to announcements of recommendation updates and should check the CDC influenza website periodically for additional information (http://www.cdc.gov/flu).

*Trivalent inactivated influenza vaccine.
†Live, attenuated influenza vaccine.

FIGURE 5-6 Algorithm for determining recommended influenza immunization actions for children. (Modified with permission from the American Academy of Pediatrics' Committee on Infectious Diseases: Prevention of influenza: recommendations for influenza immunization of children, 2006-2007, *Pediatrics* 119:846-51.315, 2007.)

HIV Testing and Postexposure Prophylaxis

RECOMMENDATIONS FOR HIV TESTING OF ADULTS, ADOLESCENTS, AND PREGNANT WOMEN

RECOMMENDATIONS FOR ADULTS AND ADOLESCENTS*

The CDC recommends that diagnostic human immunodeficiency virus (HIV) testing and opt-out HIV screening be a part of routine clinical care in all health care settings while also preserving the patient's option to decline HIV testing and ensuring a provider-patient relationship conducive to optimal clinical and preventive care. The recommendations are intended for providers in all health care settings, including hospital emergency departments, urgent-care clinics, inpatient services, sexually transmitted disease (STD) clinics or other venues offering clinical STD services, tuberculosis (TB) clinics, substance abuse treatment clinics, other public health clinics, community clinics, correctional health care facilities, and primary care settings. The guidelines address HIV testing in health care settings only; they do not modify existing guidelines concerning HIV counseling, testing, and referral for persons at high risk for HIV who seek or receive HIV testing in nonclinical settings (e.g., community-based organizations, outreach settings, or mobile vans).

SCREENING FOR HIV INFECTION

- In all health care settings, screening for HIV infection should be performed routinely for all patients aged 13 to 64 years. Health care providers should initiate screening unless prevalence of undiagnosed HIV infection in their patients has been documented to be less than 0.1%. In the absence of existing data for HIV prevalence, health care providers should initiate voluntary HIV screening until they establish that the diagnostic yield is less than 1 per 1000 patients screened, at which point such screening is no longer warranted.
- All patients initiating treatment for TB should be screened routinely for HIV infection.
- All patients seeking treatment for STDs, including all patients visiting STD clinics, should be screened routinely for HIV during each visit for a new complaint, regardless of whether the patient is known or suspected to have specific behavior risks for HIV infection.

REPEAT SCREENING

- Health care providers should subsequently test all persons likely to be at high risk for HIV at least annually. Persons likely to be at high risk include users of injection drugs and their sex partners, persons who exchange sex for money or drugs, sex partners of persons who are HIV infected, and men who have sex with men (MSM) or heterosexual persons who themselves or whose sex partners have had more than one sex partner since their most recent HIV test.
- Health care providers should encourage patients and their prospective sex partners to be tested before initiating a new sexual relationship.
- Repeat screening of persons not likely to be at high risk for HIV should be performed on the basis of clinical judgment.
- Unless recent HIV test results are immediately available, any person whose blood or body fluid is the source of an occupational exposure for a health care provider should be informed of the incident and tested for HIV infection at the time the exposure occurs.

CONSENT AND PRETEST INFORMATION

- Screening should be voluntary and undertaken only with the patient's knowledge and understanding that HIV testing is planned.
- Patients should be informed orally or in writing that HIV testing will be performed unless they decline (opt-out screening). Oral or written information should include an explanation of HIV infection and the meanings of positive and negative test results, and the patient should be offered an opportunity to ask questions and decline testing. With such notification, consent for HIV screening should be incorporated into the patient's general informed consent for medical care on the same basis as are other screening or diagnostic tests; a separate consent form for HIV testing is not recommended.
- Easily understood informational materials should be made available in the languages of the commonly encountered populations within the service area. The competence of interpreters and bilingual staff to provide language assistance to patients with limited English proficiency must be ensured.
- If a patient declines an HIV test, this decision should be documented in the medical record.

DIAGNOSTIC TESTING FOR HIV INFECTION

- All patients with signs or symptoms consistent with HIV infection or an opportunistic illness characteristic of acquired immunodeficiency syndrome (AIDS) should be tested for HIV.
- Clinicians should maintain a high level of suspicion for acute HIV infection in all patients who have a compatible clinical syndrome and who report recent high-risk behavior. When acute retroviral syndrome is a possibility, a plasma RNA test should be used in conjunction with an HIV antibody test to diagnose acute HIV infection.
- Patients or persons responsible for the patient's care should be notified orally that testing is planned, advised of the indication for testing and the implications of positive and negative test results, and offered an opportunity to ask questions and decline testing. With such notification, the patient's general consent for medical care is considered sufficient for diagnostic HIV testing.

HIV SCREENING FOR PREGNANT WOMEN AND THEIR INFANTS*

UNIVERSAL OPT-OUT SCREENING

- All pregnant women in the United States should be screened for HIV infection.
- Screening should occur after a woman is notified that HIV screening is recommended for all pregnant patients and that she will receive an HIV test as part of the routine panel of prenatal tests unless she declines (opt-out screening).
- HIV testing must be voluntary and free from coercion. No woman should be tested without her knowledge.
- Pregnant women should receive oral or written information that includes an explanation of HIV infection, a description of interventions that can reduce HIV transmission from mother to infant, and the meanings of positive and negative test results. They should be offered an opportunity to ask questions and decline testing.
- No additional process or written documentation of informed consent beyond what is required for other routine prenatal tests should be required for HIV testing.
- If a patient declines an HIV test, this decision should be documented in the medical record.

ADDRESSING REASONS FOR DECLINING TESTING

- Providers should discuss and address reasons for declining an HIV test (e.g., lack of perceived risk, fear of the disease, and concerns regarding partner violence or potential stigma or discrimination).
- Women who decline an HIV test because they have had a previous negative test result should be informed of the importance of retesting during each pregnancy.
- Logistical reasons for not testing (e.g., scheduling) should be resolved.
- Certain women who initially decline an HIV test might accept at a later date, especially if their concerns are discussed. Certain women will continue to decline testing, and their decisions should be respected and documented in the medical record.

TIMING OF HIV TESTING

- To promote informed and timely therapeutic decisions, health care providers should test women for HIV as early as possible during each pregnancy. Women who decline the test early in prenatal care should be encouraged to be tested at a subsequent visit.

MMWR 57(RR-10), 2008.

- A second HIV test during the third trimester, preferably less than 36 weeks of gestation, is cost effective even in areas of low HIV prevalence and may be considered for all pregnant women. A second HIV test during the third trimester is recommended for women who meet one or more of the following criteria:
  - Women who receive health care in jurisdictions with elevated incidence of HIV or AIDS among women aged 15 to 45 years. In 2004, these jurisdictions included Alabama, Connecticut, Delaware, the District of Columbia, Florida, Georgia, Illinois, Louisiana, Maryland, Massachusetts, Mississippi, Nevada, New Jersey, New York, North Carolina, Pennsylvania, Puerto Rico, Rhode Island, South Carolina, Tennessee, Texas, and Virginia.[†]
  - Women who receive health care in facilities in which prenatal screening identifies at least one pregnant woman who is infected with HIV per 1000 women screened.
  - Women who are known to be at high risk for acquiring HIV (e.g., users of injection drugs and their sex partners, women who exchange sex for money or drugs, women who are sex partners of persons who are infected with HIV, and women who have had a new or more than one sex partner during this pregnancy).
  - Women who have signs or symptoms consistent with acute HIV infection. When acute retroviral syndrome is a possibility, a plasma RNA test should be used in conjunction with an HIV antibody test to diagnose acute HIV infection.

[†]A second HIV test in the third trimester is as cost effective as other common health interventions when HIV incidence among women of childbearing age is ≥17 HIV cases per 100,000 person-years. In 2004, in jurisdictions with available data on HIV case rates, a rate of 17 new HIV diagnoses per year per 100,000 women aged 15 to 45 years was associated with an AIDS case rate of at least nine AIDS diagnoses per year per 100,000 women aged 15 to 45 years (CDC, unpublished data, 2005). As of 2004, the jurisdictions listed above exceeded these thresholds. The list of specific jurisdictions where a second test in the third trimester is recommended will be updated periodically based on surveillance data.

RAPID TESTING DURING LABOR

- Any woman with undocumented HIV status at the time of labor should be screened with a rapid HIV test unless she declines (opt-out screening).
- Reasons for declining a rapid test should be explored (see "Addressing Reasons for Declining Testing").
- Immediate initiation of appropriate antiretroviral prophylaxis should be recommended to women on the basis of a reactive rapid test result without waiting for the result of a confirmatory test.

POSTPARTUM/NEWBORN TESTING

- When a woman's HIV status is still unknown at the time of delivery, she should be screened immediately postpartum with a rapid HIV test unless she declines (opt-out screening).
- When the mother's HIV status is unknown postpartum, rapid testing of the newborn as soon as possible after birth is recommended so that antiretroviral prophylaxis can be offered to infants exposed to HIV. Women should be informed that identifying HIV antibodies in the newborn indicates that the mother is infected.
- For infants whose HIV exposure status is unknown and who are in foster care, the person legally authorized to provide consent should be informed that rapid HIV testing is recommended for infants whose biologic mothers have not been tested.
- The benefits of neonatal antiretroviral prophylaxis are best realized when it is initiated within 12 hours after birth.

CONFIRMATORY TESTING

- Whenever possible, uncertainties regarding laboratory test results indicating HIV infection status should be resolved before final decisions are made regarding reproductive options, antiretroviral therapy, cesarean delivery, or other interventions.
- If the confirmatory test result is not available before delivery, immediate initiation of appropriate antiretroviral prophylaxis should be recommended to any pregnant patient whose HIV screening test result is reactive to reduce the risk for perinatal transmission.

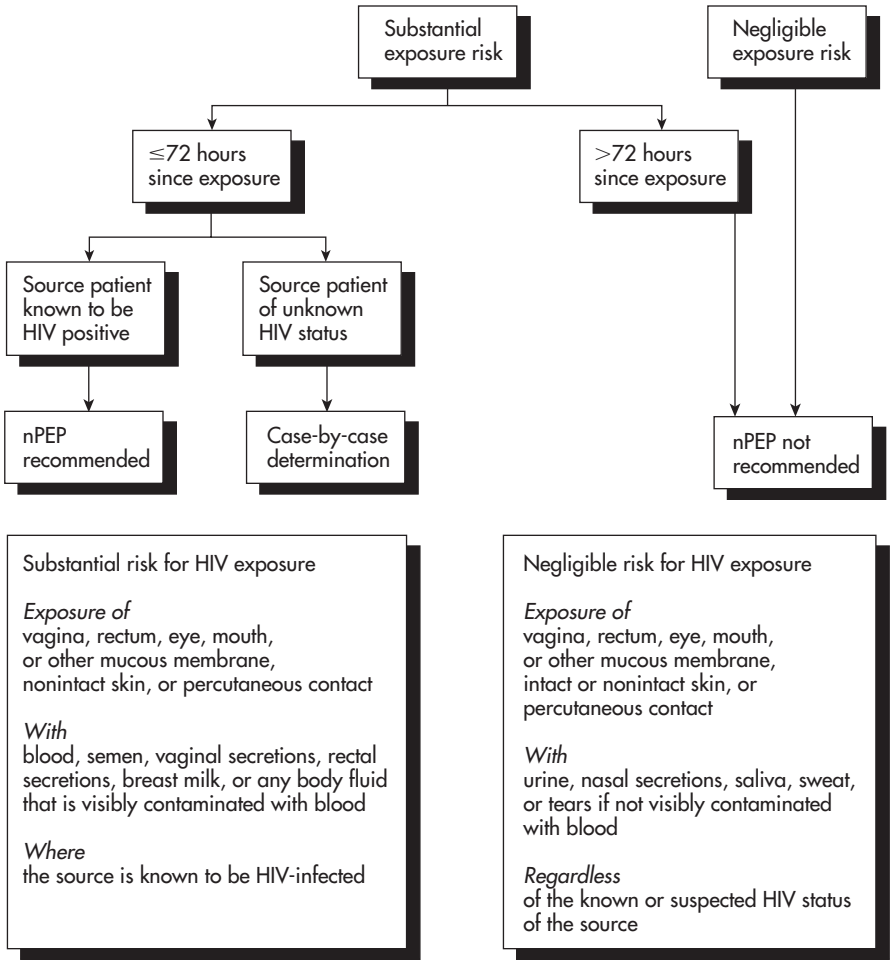


FIGURE 5-7 Algorithm for evaluation and treatment of possible nonoccupational HIV exposure. *nPEP,* Nonoccupational postexposure prophylaxis. (Modified from *MMWR* 54[RR-2], 2005.)

TABLE 5-31 HIV Exposure, Estimated Per-Act Risk

Exposure Route	Risk per 10,000 Exposures to an Infected Source
Blood transfusion	9000
Needle-sharing injection drug use	67
Receptive anal intercourse	50
Percutaneous needle stick	30
Receptive penile-vaginal intercourse	10
Insertive anal intercourse	6.5
Insertive penile-vaginal intercourse	5
Receptive oral intercourse	1
Insertive oral intercourse	0.5

Modified from *MMWR* 54(RR-2), 2005.
Estimates of risk for transmission from sexual exposures assume no condom use.
Source refers to oral intercourse performed on a man.

TABLE 5-32 Regimens for 28-Day Postexposure Prophylaxis for HIV Infection*

Regimen	Dose	Daily Pill Burden† *no.*	Advantages	Disadvantages
Two-Drug Regimens				
Tenofovir–emtricitabine (Truvada)‡	One tablet (300 mg of tenofovir with 200 mg of emtricitabine) once daily	1	Well-tolerated; once-daily dosing	Potential nephrotoxicity
Zidovudine–lamivudine (Combivir)§	One tablet (300 mg of zidovudine with 150 mg of lamivudine) twice daily	2	Preferred in pregnancy	Twice-daily dosing; less well-tolerated than tenofovir–emtricitabine (nausea, asthenia, neutropenia, anemia, abnormal liver-enzyme levels)
Three-Drug Regimens¶				
Ritonavir–lopinavir (Kaletra) (plus either tenofovir–emtricitabine or zidovudine–lamivudine)	Two tablets (50 mg of ritonavir with 200 mg of lopinavir per tablet) twice daily, or four tablets once daily	5 or 6	Either once-daily or twice-daily dosing; one copayment; no refrigeration required; most experience in pregnancy; high genetic barrier to resistance	Gastrointestinal side effects such as diarrhea; may cause elevated liver-enzyme levels or hepatitis
Ritonavir plus atazanavir (plus either tenofovir–emtricitabine or zidovudine–lamivudine)	100 mg of ritonavir plus 300 mg of atazanavir once daily	3 or 4	Once-daily dosing; well tolerated	Ritonavir must be refrigerated; potential for asymptomatic jaundice, renal stones; may cause elevated liver-enzyme levels or hepatitis
Ritonavir plus darunavir (plus either tenofovir–emtricitabine or zidovudine–lamivudine)	100 mg of ritonavir plus two tablets, each containing 400 mg of darunavir, once daily	4 or 5	Once-daily dosing; high genetic barrier to resistance	Ritonavir must be refrigerated; gastrointestinal side effects; may cause elevated liver-enzyme levels or hepatitis

*Tenofovir, emtricitabine, and lamivudine all have activity against hepatitis B. Patients with chronic active hepatitis B (i.e., patients who are positive for hepatitis B surface antigen) may have flares of hepatitis on withdrawal of these agents at the completion of postexposure prophylaxis treatment. Referral to a hepatitis specialist or serial monthly monitoring of liver-enzyme levels for up to 6 months after treatment should be considered.

†The daily pill burden in the three-drug regimens depends on which two-drug regimen is chosen.

‡The dose of tenofovir–emtricitabine should be reduced to one tablet every 48 hours in patients with a creatinine clearance of 30 to 49 ml per minute. Tenofovir–emtricitabine is not recommended in patients with a creatinine clearance of less than 30 ml per minute or in patients who are undergoing hemodialysis; see the guidelines from the Department of Health and Human Services for considerations regarding doses of individual agents in patients with advanced renal dysfunction.

§Zidovudine–lamivudine is not recommended in patients with a creatinine clearance of less than 50 ml per minute; see the guidelines from the Department of Health and Human Services for considerations regarding doses of individual agents in patients with renal dysfunction.

¶The boosting agent ritonavir is not considered to be an active drug in tabulating the number of agents in the three-drug regimen.

From Landovitz RJ, Currier JS: Postexposure prophylaxis for HIV infection, *N Engl J Med* 361:1768-75, 2009.

TABLE 5-33 Highly Active Antiretroviral Therapy Medications, Adult Dosage, and Side Effects

Medication	Adult Dosage*	Side Effects and Toxicities
Combination Tablets		
Lopinavir/ritonavir (Kaletra)‡	3 tablets twice daily 400 mg lopinavir/100 mg ritonavir	Diarrhea, nausea, vomiting; asthenia; elevated transaminases; hyperglycemia; fat redistribution; lipid abnormalities; possible increased bleeding in persons with hemophilia; pancreatitis
Zidovudine/lamivudine (Combivir)	1 tablet twice daily 300 mg zidovudine/150 mg lamivudine	See following individual medications
Zidovudine/lamivudine/abacavir (Trizivir)	1 tablet twice daily 300 mg zidovudine/150 mg lamivudine/ 300 mg abacavir	See following individual medications
Lamivudine/abacavir (Epzicom)	1 tablet once daily 300 mg lamivudine/600 mg abacavir	See following individual medications
Emtricitabine/tenofovir (Truvada)	1 tablet once daily 200 mg emtricitabine/300 mg tenofovir	See following individual medications
Single Agents		
Nucleoside and nucleotide reverse transcriptase inhibitors (side effects as a class: lactic acidosis, severe hepatomegaly with steatosis, including some fatal cases)		
Abacavir (Ziagen, ABC)‡	300 mg twice daily or 600 mg once daily	Severe hypersensitivity reaction (can be fatal); nausea; vomiting
Didanosine (Videx, ddl)‡	>60 kg (132 lb) body weight: 200 mg twice daily or 400 mg daily; if with tenofovir, 250 mg/daily <60 kg (132 lb): 125 mg twice daily or 250 mg daily; if with tenofovir, dose not established Do not use with stavudine (d4T, Zerit) during pregnancy; avoid ddl/d4T combination in general because of increased risk for adverse events (e.g., neuropathy, pancreatitis, and hyperlactatemia)	Pancreatitis; nausea, diarrhea; peripheral neuropathy
Emtricitabine (Emtriva, FTC)	200 mg once daily	Minimal toxicity; lactic acidosis and hepatic steatosis a rare but possibly life-threatening event
Lamivudine (Epivir, 3TC)‡	150 mg twice daily or 300 mg once daily	Minimal toxicity; lactic acidosis and hepatic steatosis a rare but possibly life-threatening event
Stavudine (Zerit, d4T)‡	>60 kg (132 lb) body weight: 40 mg twice daily <60 kg (132 lb) body weight: 30 mg twice daily Do not use with didanosine (ddl, Videx) during pregnancy; avoid ddl/d4T combination in general because of increased risk of adverse events (e.g., neuropathy, pancreatitis, and hyperlactatemia)	Pancreatitis; peripheral neuropathy; rapidly progressive ascending neuromuscular weakness (rare)
Tenofovir (Viread)	300 mg daily	Nausea, vomiting, diarrhea; headache; asthenia; flatulence; renal impairment
Zidovudine (Retrovir, AZT)‡	200 mg three times daily or 300 mg twice daily	Bone marrow suppression (anemia, neutropenia); gastrointestinal intolerance; headache; insomnia; asthenia; and myopathy
Nonnucleoside reverse transcriptase inhibitors (side effects as a class: Stevens-Johnson syndrome)		
Efavirenz (Sustiva)	600 mg daily at bedtime	Rash; central nervous system symptoms (e.g., dizziness, impaired concentration, insomnia, and abnormal dreams); transaminase elevation; false-positive cannabinoid test
Protease inhibitors (side effects as a class: gastrointestinal intolerance, hyperlipidemia, hyperglycemia, diabetes, fat redistribution, and possible increased bleeding in hemophiliacs; do not use during known or possible pregnancy)		
Atazanavir (Reyataz)	400 mg once daily; if administered with tenofovir plus ritonavir, 300 mg once daily	Indirect hyperbilirubinemia; prolonged PR interval (use caution in patients with underlying cardiac conduction defects or on concomitant medications that can cause PR prolongation)
Fosamprenavir (Lexiva)‡	1400 mg twice daily	Gastrointestinal intolerance, nausea, vomiting, diarrhea; rash; elevated transaminases; headache
Indinavir (Crixivan)	800 mg q8h With ritonavir (might increase risk for renal adverse events): 800 mg indinavir and 100 mg ritonavir q12h or 800 mg indinavir and 200 mg ritonavir every q12h	Gastrointestinal intolerance, nausea; nephrolithiasis; headache; asthenia; blurred vision; metallic taste; thrombocytopenia; hemolytic anemia; indirect hyperbilirubinemia (inconsequential)
Nelfinavir (Viracept)‡	750 mg three times daily or one 250 mg twice daily	Diarrhea; elevated transaminases
Ritonavir (Norvir)‡	See doses used in combination with other specific protease inhibitors	Gastrointestinal intolerance; nausea, vomiting, diarrhea; paresthesias; hepatitis; pancreatitis; asthenia; taste perversion; many drug interactions
Saquinavir (hard-gel capsule) (Invirase)	With ritonavir: 400 mg saquinavir and 400 mg ritonavir twice daily or 1000 mg saquinavir and 100 mg ritonavir twice daily	Gastrointestinal intolerance; nausea, diarrhea; headache; elevated transaminases
Saquinavir (soft-gel capsule) (Fortavase)	With ritonavir: 400 mg saquinavir and 400 mg ritonavir twice daily or 1000 mg saquinavir and 100 mg ritonavir twice daily	Gastrointestinal intolerance; nausea, diarrhea; abdominal pain; dyspepsia; headache; elevated transaminases

TABLE 5-34 Laboratory Tests Generally Recommended for Persons after Exposure to HIV*

TEST	RECOMMENDED DURING TREATMENT		RECOMMENDED AT FOLLOW-UP		
	Baseline	Symptom-Directed†	4-6 wk	12 wk	24 wk
ELISA for HIV antibodies	Yes	Yes	Yes	Yes	Yes
Creatinine, liver function, and complete blood count with differential count	Yes	Yes	No	No	No
HIV viral load	No	Yes	No	No	No
Anti-HBs antibodies	Yes‡	No	No	No	No
HBsAg	Yes‡§	No	No	No	No
HCV antibodies	Yes	No	Yes	Yes	Yes
HCV RNA¶	No	Yes	Yes	Yes	Yes
Screening, including rapid plasma reagin test, for other sexually transmitted infections‖	Yes	Yes	No	Yes	No

*Patients who receive zidovudine plus lamivudine–based regimens should have a complete blood count and measurement of liver-enzyme levels at 2 weeks of treatment, irrespective of the presence or absence of clinical symptoms. Tenofovir plus emtricitabine–based regimens generally involve few side effects, and symptom-directed assessment of serum creatinine or liver-enzyme levels should be considered. The addition of a ritonavir-boosted protease inhibitor should be followed by symptom-directed assessment of liver-enzyme levels, serum glucose levels, or both. Anti-HBs antibodies denotes hepatitis B virus surface antibodies, ELISA enzyme-linked immunosorbent assay, HBsAg hepatitis B surface antigen, and HCV hepatitis C virus.

†Symptom-directed tests are for signs or symptoms of toxic effects (rash, nausea, vomiting, or abdominal pain) or HIV seroconversion (fever, fatigue, lymphadenopathy, rash, or oral or genital ulcers).

‡If tests for anti-HBs antibodies and HBsAg are both negative, a vaccination series against HBV infection should be initiated and completed.

§If the patient is HBsAg-positive, he or she should have monthly follow-up of liver-function tests after discontinuation of postexposure prophylactic regimens containing tenofovir, lamivudine, or emtricitabine; referral to a specialist in viral hepatitis should be considered.

¶HCV RNA testing may identify early HCV seroconversion; early detection and treatment during acute HCV infection may avert or ameliorate chronic disease. Data are from Dienstag and McHutchison.

‖Rapid plasma reagin testing and testing of urethral-swab and rectal-swab specimens for gonorrhea and chlamydia and of pharyngeal-swab specimens for gonorrhea should be performed as appropriate, according to the patient's sexual risk-taking behaviors and the type of exposure to HIV.

From Landovitz RJ, Currier JS: *Postexposure Prophylaxis for HIV infection,* N Engl J Med 361:1768-75, 2009

BOX 5-4 Situations for Which Expert Consultation for HIV Postexposure Prophylaxis Is Advised*

- Delayed (i.e., later than 24-36 hours) exposure report
  - The interval after which there is no benefit from postexposure prophylaxis (PEP) is undefined
- Unknown source (e.g., needle in sharps disposal container or laundry)
  - Decide use of PEP on a case-by-case basis
  - Consider the severity of the exposure and the epidemiologic likelihood of HIV exposure
  - Do not test needles or other sharp instruments for HIV
- Known or suspected pregnancy in the exposed person
  - Does not preclude the use of optimal PEP regimens
  - Do not deny PEP solely on the basis of pregnancy
- Resistance of the source virus to antiretroviral agents
  - Influence of drug resistance on transmission risk is unknown
  - Selection of drugs to which the source person's virus is unlikely to be resistant is recommended if the source person's virus is known or suspected to be resistant to one or more of the drugs considered for the PEP regimen
  - Resistance testing of the source person's virus at the time of the exposure is not recommended
- Toxicity of the initial PEP regimen
  - Adverse symptoms such as nausea and diarrhea are common with PEP
  - Symptoms often can be managed without changing the PEP regimen by prescribing antimotility and/or antiemetic agents
  - Modification of dose intervals (i.e., administering a lower dose of drug more frequently throughout the day, as recommended by the manufacturer) in other situations might help alleviate symptoms

National Clinicians' Postexposure Prophylaxis Hotline (PEPline) Run by University of California–San Francisco/San Francisco General Hospital staff; supported by the Health Resources and Services Administration, Ryan White CARE Act, HIV/AIDS Bureau, AIDS Education and Training Centers, and CDC	Phone: 888-448-4911 Internet: http://www.ucsf.edu/hivcntr
Needlestick! A website to help clinicians manage and document occupational blood and body fluid exposures. Developed and maintained by the University of California, Los Angeles (UCLA), Emergency Medicine Center, UCLA School of Medicine, and funded in part by CDC and the Agency for Healthcare Research and Quality	Internet: http://www.needlestick.mednet.ucla.edu
Hepatitis Hotline	Phone: 888-443-7232 Internet: http://www.cdc.gov/ncidod/diseases/hepatitis/index.htm
Reporting to CDC: Occupationally acquired HIV infections and failures of PEP	Phone: 800-893-0485
HIV Antiretroviral Pregnancy Registry	Phone: 800-258-4263 Fax: 800-800-1052 Address: 1410 Commonwealth Dr., Suite 215, Wilmington, NC 28405 Internet: http://www.glaxowellcome.com/preg_reg/antiretroviral
Food and Drug Administration Report unusual or severe toxicity to antiretroviral agents	Phone: 800-332-1088 Address: MedWatch, HF-2, FDA, 5600 Fishers Lane, Rockville, MD 20857 Internet: http://www.fda.gov/medwatch
HIV/AIDS Treatment Information Service	Internet: http://www.hivatis.org

BOX 5-6 Management of Occupational Blood Exposures

Provide immediate care to the exposure site:
- Wash wounds and skin with soap and water
- Flush mucous membranes with water

Determine risk associated with exposure:
- Type of fluid (e.g., blood, visibly bloody fluid, other potentially infectious fluid or tissue, and concentrated virus)
- Type of exposure (e.g., percutaneous injury, mucous membrane or nonintact skin exposure, and bites resulting in blood exposure)

Evaluate exposure source:
- Assess the risk of infection using available information
- Test known sources for HBsAg, anti-HCV, and HIV antibodies (consider using rapid testing)
- For unknown sources, assess risk of exposure to HBV, HCV, or HIV infection
- Do not test discarded needles or syringes for virus contamination

Evaluate the exposed person:
- Assess immune status for HBV infection (i.e., by history of hepatitis B vaccination and vaccine response)

Give PEP for exposures posing risk of infection transmission:
- HBV: See Table 5-26
- HCV: PEP not recommended
- HIV: See Tables 5-34, 5-35, and 5-36 and Figure 5-7
  - Initiate PEP as soon as possible, preferably within hours of exposure
  - Offer pregnancy testing to all women of childbearing age not known to be pregnant
  - Seek expert consultation if viral resistance is suspected
  - Administer PEP for 4 weeks if tolerated

Perform follow-up testing and provide counseling:
- Advise exposed persons to seek medical evaluation for any acute illness occurring during follow-up

HBV exposures
- Perform follow-up anti-HBs testing in persons who receive hepatitis B vaccine
  - Test for anti-HBs 1 to 2 months after last dose of vaccine
  - Anti-HBs response to vaccine cannot be ascertained if HBIG was received in the previous 3 to 4 months

HCV exposures
- Perform baseline and follow-up testing for anti-HCV and alanine aminotransferase 4 to 6 months after exposures
- Perform HCV RNA at 4 to 6 weeks if earlier diagnosis of HCV infection desired
- Confirm repeatedly reactive anti-HCV enzyme immunoassays with supplemental tests

HIV exposures
- Perform HIV-antibody testing for at least 6 months after exposure (e.g., at baseline, 6 weeks, 3 months, and 6 months)
- Perform HIV-antibody testing if illness compatible with an acute retroviral syndrome occurs
- Advise exposed persons to use precautions to prevent secondary transmission during the follow-up period
- Evaluate exposed persons taking PEP within 72 hr after exposure and monitor for drug toxicity for at least 2 weeks

HBIG, Hepatitis B immune globulin; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HIV,* human immunodeficiency virus; *PEP,* post-exposure prophylaxis; *RNA,* ribonucleic acid.

Endocarditis Prophylaxis*

TABLE 5-35 Cardiac Conditions Associated with the Highest Risk of Adverse Outcome from Endocarditis for Which Prophylaxis with Dental Procedures Is Recommended

Prosthetic cardiac valve
Previous infective endocarditis
CHD*
Unrepaired cyanotic CHD, including palliative shunts and conduits
Completely repaired congenital heart defect with prosthetic material or device, whether placed by surgery or by catheter intervention, during the first 6 mo after the procedure†
Repaired CHD with residual defects at the site or adjacent to the site of a prosthetic patch or prosthetic device (that inhibit endothelialization)
Cardiac transplant recipients who develop cardiac valvulopathy

CHD, Congenital heart disease.
*Except for the conditions listed above, antibiotic prophylaxis is no longer recommended for any other form of CHD.
†Prophylaxis is recommended because endothelialization of prosthetic material occurs within 6 mo after the procedure.

TABLE 5-36 Dental Procedures for Which Endocarditis Prophylaxis Is Recommended for Patients in Table 5-35

All dental procedures that involve manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa*

*The following procedures and events do not need prophylaxis: routine anesthetic injections through noninfected tissue, taking dental radiographs, placement of removable prosthodontic or orthodontic appliances, adjustment of orthodontic appliances, placement of orthodontic brackets, shedding of deciduous teeth, and bleeding from trauma to the lips or oral mucosa.

TABLE 5-37 Regimens for a Dental Procedure

	REGIMEN: SINGLE DOSE 30-60 MIN BEFORE PROCEDURE		
Situation	**Agent**	**Adults**	**Children**
Oral	Amoxicillin	2 g	50 mg/kg
Unable to take oral medication	Ampicillin	2 g IM or IV	50 mg/kg IM or IV
	OR		
	Cefazolin or ceftriaxone*	1 g IM or IV	50 mg/kg IM or IV
Allergic to penicillins or ampicillin, oral	Cephalexin*†	2 g	50 mg/kg
	OR		
	Clindamycin	600 mg	20 mg/kg
	OR		
	Azithromycin or clarithromycin	500 mg	15 mg/kg
Allergic to penicillins or ampicillin and unable to take oral medicine	Cefazolin or ceftriaxone†	1 g IM or IV	50 mg/kg IM or IV
	OR		
	Clindamycin	600 mg IM or IV	20 mg/kg IM or IV

IM, Intramuscular; *IV,* intravenous.
*Or other first-generation or second-generation oral cephalosporin in equivalent adult or pediatric dosage.
†Cephalosporins should not be used in an individual with a history of anaphylaxis, angioedema, or urticaria with penicillins or ampicillin.

*From Prevention of infective endocarditis. A guideline from the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee, Council on Cardiovascular Disease in the Young, and the Council on Clinical Cardiology, Council on Cardiovascular Surgery and Anesthesia, and the Quality of Care and Outcomes Research Interdisciplinary Working Group. *Circulation* published online Apr 19, 2007, DOI: 10.1161/CIRCULATIONAHA.106.183095. TABLE 5-38 Summary of Major Changes in Updated Recommendations

We concluded that bacteremia resulting from daily activities is much more likely to cause IE than bacteremia associated with a dental procedure.

We concluded that only an extremely small number of cases of IE might be prevented by antibiotic prophylaxis even if prophylaxis is 100% effective.

Antibiotic prophylaxis is not recommended based solely on an increased lifetime risk of acquisition of IE.

Limit recommendations for IE prophylaxis only to those conditions listed in Table 5-37.

Antibiotic prophylaxis is no longer recommended for any other form of CHD, except for the conditions listed in Table 5-37.

Antibiotic prophylaxis is recommended for all dental procedures that involve manipulation of gingival tissues or periapical region of teeth or perforation of oral mucosa only for patients with underlying cardiac conditions associated with the highest risk of adverse outcome from IE (see Table 5-37).

Antibiotic prophylaxis is recommended for procedures on respiratory tract or infected skin, skin structures, or musculoskeletal tissue only for patients with underlying cardiac conditions associated with the highest risk of adverse outcome from IE (see Table 5-37).

Antibiotic prophylaxis solely to prevent IE is not recommended for GU or GI tract procedures.

The writing group reaffirms the procedures noted in the 1997 prophylaxis guidelines for which endocarditis prophylaxis is not recommended and extends this to other common procedures, including ear and body piercing, tattooing, and vaginal delivery and hysterectomy.

A guide to the clinical preventive services described is available online at http://www.ahrq.gov/clinic/pocketgd07/.
CHD, Congenital heart disease; *GI,* gastrointestinal; *GU,* genitourinary; *IE,* infective endocarditis.

PART C • GUIDE TO CLINICAL PREVENTIVE SERVICES*

1. Cancer
   a. Screening for bladder cancer in adults
   b. Genetic risk assessment and BRCA mutation testing for breast and ovarian cancer susceptibility
   c. Screening for breast cancer
   d. Screening for cervical cancer
   e. Screening for colorectal cancer
   f. Lung cancer screening
   g. Screening for ovarian cancer
   h. Screening for pancreatic cancer
   i. Screening for prostate cancer
   j. Counseling to prevent skin cancer
   k. Screening for testicular cancer
2. Heart and vascular diseases
   a. Screening for abdominal aortic aneurysm
   b. Aspirin for the primary prevention of cardiovascular events
   c. Screening for coronary heart disease
   d. Screening for lipid disorders in adults
   e. Screening for peripheral arterial disease
3. Infectious diseases
   a. Screening for asymptomatic bacteriuria
   b. Screening for chlamydial infection
   c. Screening for genital herpes
   d. Screening for gonorrhea
   e. Screening for hepatitis B virus infection
   f. Screening for hepatitis C in adults
   g. Screening for syphilis infection
4. Injury and violence
   a. Screening for family and intimate partner violence
5. Mental health conditions and substance abuse
   a. Screening and behavioral counseling interventions in primary care to reduce alcohol misuse
   b. Screening for dementia
   c. Screening for depression
   d. Screening for suicide risk
6. Counseling to prevent tobacco use and tobacco-caused disease
7. Metabolic, nutritional, and endocrine conditions
   a. Behavioral counseling in primary care to promote a healthy diet
   b. Hormone therapy for the prevention of chronic conditions in postmenopausal women
   c. Screening for obesity in adults
   d. Behavioral counseling in primary care to promote physical activity
   e. Screening for thyroid disease
   f. Screening for type 2 diabetes mellitus in adults
8. Musculoskeletal conditions
   a. Primary care interventions to prevent low back pain in adults
   b. Screening for osteoporosis in postmenopausal women
9. Vision disorders
   a. Screening for glaucoma

Recommendations of the U.S. Preventive Services Task Force

The recommendation statements in this section are abridged. To view the full recommendation statements or recommendation statements published after 2005, go to **http://www.ahrq.gov/clinic/uspstf/uspstopics.htm.** The U.S. Preventive Services Task Force's (USPSTF) **Interactive Preventive Services Selector** for PDAs, and its companion web-based tool, is updated frequently with new USPSTF recommendations. Users can search recommendations by patient age, sex, and pregnancy status. To download, go to **http://pda.ahrq.gov.**

Recommendations made by the USPSTF are independent of the U.S. Government. They should not be construed as an official position of AHRQ or the U.S. Department of Health and Human Services.

HOW THE U.S. PREVENTIVE SERVICES TASK FORCE GRADES ITS RECOMMENDATIONS

The U.S. Preventive Services Task Force (USPSTF) grades its recommendations based on the strength of evidence and magnitude of net benefit (benefits minus harms).

A. The USPSTF strongly recommends that clinicians provide [the service] to eligible patients. The USPSTF found good evidence that [the service] improves important health outcomes and concludes that benefits substantially outweigh harms.

B. The USPSTF recommends that clinicians provide [the service] to eligible patients. The USPSTF found at least fair evidence that [the service] improves important health outcomes and concludes that benefits outweigh harms.

C. The USPSTF makes no recommendation for or against routine provision of [the service]. The USPSTF found at least fair evidence that [the service] can improve health outcomes but concludes that the balance of benefits and harms is too close to justify a general recommendation.

D. The USPSTF recommends against routinely providing [the service] to asymptomatic patients. The USPSTF found at least fair evidence that [the service] is ineffective or that harms outweigh benefits.

E. The USPSTF concludes that the evidence is insufficient to recommend for or against routinely providing [the service]. Evidence that [the service] is effective is lacking, of poor quality, or conflicting, and the balance of benefits and harms cannot be determined.

The USPSTF grades the quality of the overall evidence for a service on a 3-point scale (good, fair, poor).

Good: Evidence includes consistent results from well-designed, well-conducted studies in representative populations that directly assess effects on health outcomes.

Fair: Evidence is sufficient to determine effects on health outcomes, but the strength of the evidence is limited by the number, quality, or consistency of the individual studies, generalizability to routine practice, or indirect nature of the evidence on health outcomes.

Poor: Evidence is insufficient to assess the effects on health outcomes because of limited number or power of studies, important flaws in their design or conduct, gaps in the chain of evidence, or lack of information on important health outcomes.

Strength of Overall Evidence and Estimate of Net Benefit Determine the Grade

Strength of Overall Evidence of Effectiveness	Estimate of Net Benefit (Benefit Minus Harms)			
	Substantial	Moderate	Small	Zero/ Negative
Good	A	B	C	D
Fair	B	B	C	D
Poor	I – Insufficient Evidence			

Guide to clinical preventive services, 2007: recommendations of the U.S. Preventive Services Task Force. AHRQ Publication No. 07.05100, September 2007. Agency for Healthcare Research and Quality, Rockville, MD. http://www.ahrq.gov/clinic/pocketgd.07/

1. CANCER

A. SCREENING FOR BLADDER CANCER IN ADULTS

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine screening for bladder cancer in adults. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- Bladder cancer is 2 to 3 times more common in men than in women and is unusual before age 50. Bladder cancer is heterogeneous; it is a spectrum of conditions, most of which are not life-threatening.
- Screening tests—such as microscopic urinalysis, urine dipstick, urine cytology, or such new tests as bladder tumor antigen (BTA) or nuclear matrix protein (NMP22) immunoassay—can detect bladder cancers that are clinically unapparent. However, because of the low prevalence of bladder cancer, the positive predictive value of these tests is low.
- Smoking increases the risk for bladder cancer; about 50% of all cases of bladder cancer occur in current or former smokers. Smokers should be counseled on quitting smoking.
- People in occupations that involve exposure to chemicals used in the dye or rubber industries may also have increased risk for bladder cancer. The USPSTF did not review the evidence for targeted screening for those with occupational exposure.

B. GENETIC RISK ASSESSMENT AND BRCA MUTATION TESTING FOR BREAST AND OVARIAN CANCER SUSCEPTIBILITY

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine referral for genetic counseling or routine breast cancer susceptibility gene *(BRCA)* testing for women whose family history is not associated with an increased risk for deleterious mutations in breast cancer susceptibility gene 1 *(BRCA1)* or breast cancer susceptibility gene 2 *(BRCA2)*. *Rating: D Recommendation.*

The USPSTF recommends that women whose family history is associated with an increased risk for deleterious mutations in *BRCA1* or *BRCA2* genes be referred for genetic counseling and evaluation for *BRCA* testing. *Rating: B Recommendation.*

CLINICAL CONSIDERATIONS

- These recommendations apply to women who have not received a diagnosis of breast or ovarian cancer. They do not apply to women with a family history of breast or ovarian cancer that includes a relative with a known deleterious mutation in *BRCA1* or *BRCA2* genes; these women should be referred for genetic counseling. These recommendations do not apply to men.
- Although there currently are no standardized referral criteria, women with an increased-risk family history should be considered for genetic counseling to further evaluate their potential risks.
- Certain specific family history patterns are associated with an increased risk for deleterious mutations in the *BRCA1* or *BRCA2* gene. Both maternal and paternal family histories are important. For non-Ashkenazi Jewish women, these patterns include 2 first-degree relatives with breast cancer, 1 of whom received the diagnosis at age 50 years or younger; a combination of 3 or more first- or second-degree relatives with breast cancer regardless of age at diagnosis; a combination of both breast and ovarian cancer among first- and second-degree relatives; a first-degree relative with bilateral breast cancer; a combination of 2 or more first- or second-degree relatives with ovarian cancer regardless of age at diagnosis; a first- or second-degree relative with both breast and ovarian cancer at any age; and a history of breast cancer in a male relative.
- For women of Ashkenazi Jewish heritage, an increased-risk family history includes any first-degree relative (or 2 second-degree relatives on the same side of the family) with breast or ovarian cancer.
- About 2 percent of adult women in the general population have an increased-risk family history as defined here. Women with none of these family history patterns have a low probability of having a deleterious mutation in *BRCA1* or *BRCA2* genes.
- Computational tools are available to predict the risk for clinically important *BRCA* mutations (that is, *BRCA* mutations associated with the presence of breast cancer, ovarian cancer, or both), but these tools have not been verified in the general population. There is no empirical evidence concerning the level of risk for a *BRCA* mutation that merits referral for genetic counseling.
- Not all women with a potentially deleterious *BRCA* mutation will develop breast or ovarian cancer. In a woman who has a clinically important *BRCA* mutation, the probability of developing breast or ovarian cancer by age 70 years is estimated to be 35 percent to 84 percent for breast cancer and 10 percent to 50 percent for ovarian cancer.
- Appropriate genetic counseling helps women make informed decisions, can improve their knowledge and perception of absolute risk for breast and ovarian cancer, and can often reduce anxiety. Genetic counseling includes elements of counseling; risk assessment; pedigree analysis; and, in some cases, recommendations for testing for *BRCA* mutations in affected family members, the presenting patient, or both. It is best delivered by a suitably trained health care provider.
- A *BRCA* test is typically ordered by a physician. When done in concert with genetic counseling, the test assures the linkage of testing with appropriate management decisions. Genetic testing may lead to potential adverse ethical, legal, and social consequences, such as insurance and employment discrimination; these issues should be discussed in the context of genetic counseling and evaluation for testing.
- Among women with *BRCA1* or *BRCA2* mutations, prophylactic mastectomy or oophorectomy decreases the incidence of breast and ovarian cancer; there is inadequate evidence for mortality benefits. Chemoprevention with selective estrogen receptor modulators may decrease incidence of estrogen receptor-positive breast cancer; however, it is also associated with adverse effects, such as pulmonary embolism, deep venous thrombosis, and endometrial cancer. Most breast cancer associated with *BRCA1* mutations is estrogen receptor-negative and thus is not prevented by tamoxifen. Intensive screening with mammography has poor sensitivity, and there is no evidence of benefit of intensive screening for women with *BRCA1* or *BRCA2* gene mutations. Magnetic resonance imaging (MRI) may detect more cases of cancer, but the effect on mortality is not clear.
- Women with an increased-risk family history are at risk not only for deleterious *BRCA1* or *BRCA2* mutations but potentially for other unknown mutations as well. Women with an increased-risk family history who have negative results on tests for *BRCA1* and *BRCA2* mutations may also benefit from surgical prophylaxis.

C. SCREENING FOR BREAST CANCER

Summary of Recommendations

The U.S. Preventive Services Task Force (USPSTF) recommends screening mammography, with or without clinical breast examination (CBE), every 1-2 years for women aged 40 and older. *Rating: B Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against routine CBE alone to screen for breast cancer. *Rating: I Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against teaching or performing routine breast self-examination (BSE). *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- The precise age at which the benefits from screening mammography justify the potential harms is a subjective judgment and should take into account patient preferences. Clinicians should inform women about the potential benefits (reduced chance of dying from breast cancer), potential harms (e.g., false-positive results, unnecessary biopsies), and limitations of the test that apply to women their age. Clinicians should tell women that the balance of benefits and potential harms of mammography improves with increasing age for women between the ages of 40 and 70.
- Women who are at increased risk for breast cancer (e.g., those with a family history of breast cancer in a mother or sister, a previous breast biopsy revealing atypical hyperplasia, or first childbirth after age 30) are more likely to benefit from regular mammography than women at lower risk. The recommendation for women to begin routine screening in their 40s is strengthened by a family history of breast cancer having been diagnosed before menopause.
- The USPSTF did not examine whether women should be screened for genetic mutations (e.g., *BRCA1* and *BRCA2*) that increase the risk for developing breast cancer, or whether women with genetic mutations might benefit from earlier or more frequent screening for breast cancer.
- In the trials that demonstrated the effectiveness of mammography in lowering breast cancer mortality, screening was performed every 12-33 months. For women aged 50 and older, there is little evidence to suggest that annual mammography is more effective than mammography done every other year. For women aged 40-49, available trials also have not reported a clear advantage of annual mammography over biennial mammography. Nevertheless, some experts recommend annual mammography based on the lower sensitivity of the test and on evidence that tumors grow more rapidly in this age group.
- The precise age at which to discontinue screening mammography is uncertain. Only 2 randomized controlled trials enrolled women older than 69 and no trials enrolled women older than 74. Older women face a higher probability of developing and dying from breast cancer but also have a greater chance of dying from other causes. Women with comorbid conditions that limit their life expectancy are unlikely to benefit from screening.
- Clinicians should refer patients to mammography screening centers with proper accreditation and quality assurance standards to ensure accurate imaging and radiographic interpretation. Clinicians should adopt office systems to ensure timely and adequate follow-up of abnormal results. A listing of accredited facilities is available at http://www.fda.gov/cdrh/mammography/certified.html.
- Clinicians who advise women to perform BSE or who perform routine CBE to screen for breast cancer should understand that there is currently insufficient evidence to determine whether these practices affect breast cancer mortality, and that they are likely to increase the incidence of clinical assessments and biopsies.

D. SCREENING FOR CERVICAL CANCER

Summary of Recommendations

The U.S. Preventive Services Task Force (USPSTF) strongly recommends screening for cervical cancer in women who have been sexually active and have a cervix. *Rating: A Recommendation.*

The USPSTF recommends against routinely screening women older than age 65 for cervical cancer if they have had adequate recent screening with normal Pap smears and are not otherwise at high risk for cervical cancer (go to *Clinical Considerations*). *Rating: D Recommendation.*

The USPSTF recommends against routine Pap smear screening in women who have had a total hysterectomy for benign disease. *Rating: D Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against the routine use of new technologies to screen for cervical cancer. *Rating: I Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against the routine use of human papillomavirus (HPV) testing as a primary screening test for cervical cancer. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- The goal of cytologic screening is to sample the transformation zone, the area where physiologic transformation from columnar endocervical epithelium to squamous (ectocervical) epithelium takes place and where dysplasia and cancer arise. A meta-analysis of randomized trials supports the combined use of an extended tip spatula to sample the ectocervix and a cytobrush to sample the endocervix.[1]
- The optimal age to begin screening is unknown. Data on natural history of HPV infection and the incidence of high-grade lesions and cervical cancer suggest that screening can safely be delayed until 3 years after onset of sexual activity or until age 21, whichever comes first.[2] Although there is little value in screening women who have never been sexually active, many U.S. organizations recommend routine screening by age 18 or 21 for all women, based on the generally high prevalence of sexual activity by that age in the U.S. and concerns that clinicians may not always obtain accurate sexual histories.
- Discontinuation of cervical cancer screening in older women is appropriate, provided women have had adequate recent screening with normal Pap results. The optimal age to discontinue screening is not clear, but risk of cervical cancer and yield of screening decline steadily through middle age. The USPSTF found evidence that yield of screening was low in previously screened women after age 65. New American Cancer Society (ACS) recommendations suggest stopping cervical cancer screening at age 70. Screening is recommended in older women who have not been previously screened, when information about previous screening is unavailable, or when screening is unlikely to have occurred in the past (e.g., among women from countries without screening programs). Evidence is limited to define "adequate recent screening." The ACS guidelines recommend that older women who have had three or more documented, consecutive, technically satisfactory normal/negative cervical cytology tests, and who have had no abnormal/positive cytology tests within the last 10 years, can safely stop screening.[2]
- The USPSTF found no direct evidence that annual screening achieves better outcomes than screening every 3 years. Modeling studies suggest little added benefit of more frequent screening for most women. The majority of cervical cancers in the United States occur in women who have never been screened or who have not been screened within the past 5 years; additional cases occur in women who do not receive appropriate follow-up after an abnormal Pap smear.[3,4] Because sensitivity of a single Pap test for high-grade lesions may only be 60%-80%, however, most organizations in the United States recommend that annual Pap smears be performed until a specified number (usually two or three) are cytologically normal before lengthening the screening interval.[5] The ACS guidelines suggest waiting until age 30 before lengthening the screening interval[2]; the American College of Obstetricians and Gynecologists (ACOG) recommends that women 30 and older wait 3 yr between paps once they have had three consecutive clear tests. However, it identifies additional risk factors that might justify annual screening, including a history of cervical neoplasia, infection with HPV or other sexually transmitted diseases (STDs), or high-risk sexual behavior,[7] but data are limited to determine the benefits of these strategies.[7]
- Discontinuation of cytological screening after total hysterectomy for benign disease (e.g., no evidence of cervical neoplasia or cancer) is appropriate given the low yield of screening and the potential harms from false-positive results in this population.[7,8] Clinicians should confirm that a total hysterectomy was performed (through surgical records or inspecting for absence of a cervix); screening may be appropriate when the indications for hysterectomy are uncertain. ACS and ACOG recommend continuing cytologic screening after hysterectomy for women with a history of invasive cervical cancer or DES exposure due to increased risk for vaginal neoplasms, but data on the yield of such screening are sparse.
- A majority of cases of invasive cervical cancer occur in women who are not adequately screened.[3,4] Clinicians, hospitals, and health plans should develop systems to identify and screen the subgroup of women who have had no screening or who have had inadequate past screening.
- Newer Food and Drug Administration (FDA)-approved technologies, such as the liquid-based cytology (e.g., ThinPrep®), may have improved sensitivity over conventional Pap smear screening, but at a considerably higher cost and possibly with lower specificity. Even if sensitivity is improved, modeling studies suggest these methods are not likely to be cost-effective unless used with screening intervals of 3 years or longer. Liquid-based cytology permits testing of specimens for HPV, which may be useful in guiding management of women whose Pap smear reveals atypical squamous cells. HPV DNA testing for primary cervical cancer screening has not been approved by the FDA and its role in screening remains uncertain.

E. SCREENING FOR COLORECTAL CANCER

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) strongly recommends that clinicians screen men and women 50 years of age or older for colorectal cancer. *Rating: A Recommendation.*

CLINICAL CONSIDERATIONS

- Potential screening options for colorectal cancer include home fecal occult blood testing (FOBT), flexible sigmoid-oscopy, the combination of home FOBT and flexible sigmoid-oscopy, colonoscopy, and double-

contrast barium enema. Each option has advantages and disadvantages that may vary for individual patients and practice settings. The choice of specific screening strategy should be based on patient preferences, medical contraindications, patient adherence, and available resources for testing and follow-up. Clinicians should talk to patients about the benefits and potential harms associated with each option before selecting a screening strategy.

- The optimal interval for screening depends on the test. Annual FOBT offers greater reductions in mortality rates than biennial screening but produces more false-positive results. A 10-year interval has been recommended for colonoscopy on the basis of evidence regarding the natural history of adenomatous polyps. Shorter intervals (5 years) have been recommended for flexible sigmoidoscopy and double-contrast barium enema because of their lower sensitivity, but there is no direct evidence with which to determine the optimal interval for tests other than FOBT. Case-control studies have suggested that sigmoidoscopy every 10 years may be as effective as sigmoidoscopy performed at shorter intervals.
- The USPSTF recommends initiating screening at 50 years of age for men and women at average risk for colorectal cancer, based on the incidence of cancer above this age in the general population. In persons at higher risk (for example, those with a first-degree relative who receives a diagnosis with colorectal cancer before 60 years of age), initiating screening at an earlier age is reasonable.
- Expert guidelines exist for screening very high-risk patients, including those with a history suggestive of familial polyposis or hereditary nonpolyposis colorectal cancer, or those with a personal history of ulcerative colitis.[1] Early screening with colonoscopy may be appropriate, and genetic counseling or testing may be indicated for patients with genetic syndromes.
- The appropriate age at which colorectal cancer screening should be discontinued is not known. Screening studies have generally been restricted to patients younger than 80 years of age, with colorectal cancer mortality rates beginning to decrease within 5 years of initiating screening. Yield of screening should increase in older persons (because of higher incidence of colorectal cancer), but benefits may be limited as a result of competing causes of death. Discontinuing screening is therefore reasonable in patients whose age or comorbid conditions limit life expectancy.
- Proven methods of FOBT screening use guaiac-based test cards prepared at home by patients from three consecutive stool samples and forwarded to the clinician. Whether patients need to restrict their diet and avoid certain medications is not established. Rehydration of the specimens before testing increases the sensitivity of FOBT but substantially increases the number of false-positive test results. Neither digital rectal examination (DRE) nor the testing of a single stool specimen obtained during DRE is recommended as an adequate screening strategy for colorectal cancer.
- The combination of FOBT and sigmoidoscopy may detect more cancers and more large polyps than either test alone, but the additional benefits and potential harms of combining the 2 tests are uncertain. In general, FOBT should precede sigmoidoscopy because a positive test result is an indication for colonoscopy, obviating the need for sigmoidoscopy.
- Colonoscopy is the most sensitive and specific test for detecting cancer and large polyps but is associated with higher risks than other screening tests for colorectal cancer. These include a small risk for bleeding and risk for perforation, primarily associated with removal of polyps or biopsies performed during screening. Colonoscopy also usually requires more highly trained personnel, overnight bowel preparation, sedation, and longer recovery time, which may necessitate transportation for the patient. It is not certain whether the potential added benefits of colonoscopy relative to screening alternatives are large enough to justify the added risks and inconvenience for all patients.
- Initial costs of colonoscopy are higher than the costs of other tests. Estimates of cost-effectiveness, however, suggest that, from a societal perspective, compared with no screening, all methods of colorectal cancer screening are likely to be as cost-effective as many other clinical preventive servicesless than $30,000 per additional year of life gained.

REFERENCE

1. Winawer SJ et al: Colorectal cancer screening: clinical guidelines and rationale, *Gastroenterology* 112:594-642, 1997.

F. LUNG CANCER SCREENING

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against screening asymptomatic persons for lung cancer with either low dose computerized tomography (LDCT), chest x-ray (CXR), sputum cytology, or a combination of these tests. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- The benefit of screening for lung cancer has not been established in any group, including asymptomatic high-risk populations such as older smokers. The balance of harms and benefits becomes increasingly unfavorable for persons at lower risk, such as nonsmokers.
- The sensitivity of LDCT for detecting lung cancer is 4 times greater than the sensitivity of CXR. However, LDCT is also associated with a greater number of false-positive results, more radiation exposure, and increased costs compared with CXR.
- Because of the high rate of false-positive results, many patients will undergo invasive diagnostic procedures as a result of lung cancer screening. Although the morbidity and mortality rates from these procedures in asymptomatic individuals are not available, mortality rates due to complications from surgical interventions in symptomatic patients reportedly range from 1.3% to 11.6%; morbidity rates range from 8.8% to 44%, with higher rates associated with larger resections.
- Other potential harms of screening are potential anxiety and concern as a result of false-positive tests, as well as possible false reassurance because of false-negative results. However, these harms have not been adequately studied.

G. SCREENING FOR OVARIAN CANCER

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine screening for ovarian cancer. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- There is no existing evidence that any screening test, including CA-125, ultrasound, or pelvic examination, reduces mortality from ovarian cancer. Furthermore, existing evidence that screening can detect early-stage ovarian cancer is insufficient to indicate that this earlier diagnosis will reduce mortality.
- Because there is a low incidence of ovarian cancer in the general population (age-adjusted incidence of 17 per 100,000 women), screening for ovarian cancer is likely to have a relatively low yield. The great majority of women with a positive screening test will not have ovarian cancer (ie, they will have a false-positive result). In women at average risk, the positive predictive value of an abnormal screening test is, at best, approximately 2% (i.e., 98% of women with positive test results will not have ovarian cancer).
- The positive predictive value of an initially positive screening test would be more favorable for women at higher risk. For example, the lifetime probability of ovarian cancer increases from about 1.6% in a 35-year-old woman without a family history of ovarian cancer to about 5% if she has 1 relative and 7% if she has 2 relatives with ovarian cancer. If ongoing clinical trials show that screening has a beneficial effect on mortality rates, then women at higher risk are likely to experience the greatest benefit.

H. SCREENING FOR PANCREATIC CANCER

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine screening for pancreatic cancer in asymptomatic adults using abdominal palpation, ultrasonography, or serologic markers. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- Due to the poor prognosis of those diagnosed with pancreatic cancer, there is an interest in primary prevention. The evidence for diet-based prevention of pancreatic cancer is limited and conflicting. Some experts recommend lifestyle changes that may help to prevent pancreatic cancer, such as stopping the use of tobacco products, moderating alcohol intake, and eating a balanced diet with sufficient fruit and vegetables.
- Persons with hereditary pancreatitis may have a higher lifetime risk for developing pancreatic cancer.[1] However, the USPSTF did not review the effectiveness of screening these patients.

REFERENCE

1. Lowenfels AB et al: Hereditary pancreatitis and the risk of pancreatic cancer. **International Hereditary Pancreatitis Study Group,** *J Natl Cancer Inst* 89:442-446, 1997.

I. SCREENING FOR PROSTATE CANCER

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against routine screening for prostate cancer using prostate specific antigen (PSA) testing or digital rectal examination (DRE). *Rating: I recommendation.*

CLINICAL CONSIDERATIONS

- Prostate specific antigen (PSA) testing and digital rectal examination (DRE) can effectively detect prostate cancer in its early pathologic stages. Recent evidence suggests that radical prostatectomy can reduce prostate cancer mortality in men whose cancer is detected clinically. The balance of potential benefits (the reduction of morbidity and mortality from prostate cancer) and harms (false-positive results, unnecessary biopsies, and possible complications) of early treatment of the types of cancers found by screening, however, remains uncertain. Therefore, the benefits of screening for early prostate cancer remain unknown. Ongoing screening trials, and trials of treatment versus "watchful waiting" for cancers detected by screening, may help clarify the benefits of early detection of prostate cancer.
- Despite the absence of firm evidence of effectiveness, some clinicians may opt to perform prostate cancer screening for other reasons. Given the uncertainties and controversy surrounding prostate cancer screening, clinicians should not order the PSA test without first discussing with the patient the potential but uncertain benefits and the possible harms of prostate cancer screening. Men should be informed of the gaps in the evidence, and they should be assisted in considering their personal preferences and risk profile before deciding whether to be tested.
- If early detection improves health outcomes, the population most likely to benefit from screening will be men aged 50 to 70 who are at average risk, and men older than 45 who are at increased risk (African American men and men with a family history of a first-degree relative with prostate cancer).[1] Benefits may be smaller in Asian Americans, Hispanics, and other racial and ethnic groups that have a lower risk of prostate cancer. Older men and men with other significant medical problems who have a life expectancy of fewer than 10 years are unlikely to benefit from screening.[1]
- PSA testing is more sensitive than DRE for the detection of prostate cancer. PSA screening with the conventional cut-point of 4.0 ng/ml detects a large majority of prostate cancers; however, a significant percentage of early prostate cancers (10% to 20%) will be missed by PSA testing alone.[2] Using a lower threshold to define an abnormal PSA detects more cancers at the cost of more false positives and more biopsies. The yield of screening in terms of cancer detected declines rapidly with repeated annual testing.[1] If screening were to reduce mortality, biennial PSA screening could yield as much benefit as annual screening.

J. COUNSELING TO PREVENT SKIN CANCER

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against routine counseling by primary care clinicians to prevent skin cancer. Rating: I Recommendation.

CLINICAL CONSIDERATIONS

- Using sunscreen has been shown to prevent squamous cell skin cancer. The evidence for the effect of sunscreen use in preventing melanoma, however, is mixed. Sunscreens that block both ultraviolet A (UV-A) and ultraviolet B (UV-B) light may be more effective in preventing squamous cell cancer and its precursors than those that block only UV-B light. However, people who use sunscreen alone could increase their risk for melanoma if they increase the time they spend in the sun.
- UV exposure increases the risk for skin cancer among people with all skin types, but especially fair-skinned people. Those who sunburn readily and tan poorly, namely those with red or blond hair and fair skin that freckles or burns easily, are at highest risk for developing skin cancer and would benefit most from sun protection behaviors. The incidence of melanoma among whites is 20 times higher than it is among blacks; the incidence of melanoma among whites is about 4 times higher than it is among Hispanics.
- Observational studies indicate that intermittent or intense sun exposure is a greater risk factor for melanoma than chronic exposure. These studies support the hypothesis that preventing sunburn, especially in childhood, may reduce the lifetime risk for melanoma.
- Other measures for preventing skin cancer include avoiding direct exposure to midday sun (between the hours of 10:00 AM and 4:00 PM) to reduce exposure to ultraviolet (UV) rays and covering skin exposed to the sun (by wearing protective clothing such as broad-brimmed hats, long-sleeved shirts, long pants, and sunglasses).
- The effects of sunlamps and tanning beds on the risk for melanoma are unclear due to limited study design and conflicting results from retrospective studies.
- Only a single case-control study of skin self-examination has reported a lower risk for melanoma among patients who reported ever examining their skin over 5 years. Although results from this study suggest that skin self-examination may be effective in preventing skin cancer, these results are not definitive.

K. SCREENING FOR TESTICULAR CANCER

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine screening for testicular cancer in asymptomatic adolescent and adult males. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- The low incidence of testicular cancer and favorable outcomes in the absence of screening make it unlikely that clinical testicular examinations would provide important health benefits. Clinical examination by a physician and self-examination are the potential screening options for testicular cancer. However, little evidence is available to assess the accuracy, yield, or benefits of screening for testicular cancer.
- Although currently most testicular cancers are discovered by patients themselves or their partners, either unintentionally or by self-examination, there is no evidence that teaching young men how to examine themselves for testicular cancer would improve health outcomes, even among men at high risk, including men with a history of undescended testes or testicular atrophy.
- Clinicians should be aware of testicular cancer as a possible diagnosis when young men present to them with suggestive signs and symptoms. There is some evidence that patients who present initially with symptoms of testicular cancer are frequently diagnosed as having epididymitis, testicular trauma, hydrocele, or other benign disorders. Efforts to promote prompt assessment and better evaluation of testicular problems may be more effective than widespread screening as a means of promoting early detection.

2. HEART AND VASCULAR DISEASES

A. SCREENING FOR ABDOMINAL AORTIC ANEURYSM

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends one-time screening for abdominal aortic aneurysm (AAA) by ultrasonography in men aged 65 to 75 who have ever smoked. *Rating: B Recommendation.*

The USPSTF makes no recommendation for or against screening for AAA in men aged 65 to 75 who have never smoked. *Rating: C Recommendation.*

The USPSTF recommends against routine screening for AAA in women. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- The major risk factors for abdominal aortic aneurysm (AAA) include age (being 65 or older), male sex, and a history of ever smoking (at least 100 cigarettes in a person's lifetime). A first-degree family history of AAA requiring surgical repair also elevates a man's risk for AAA; this may also be true for women but the evidence is less certain. There is only a modest association between risk factors for atherosclerotic disease and AAA.
- Screening for AAA would most benefit those who have a reasonably high probability of having an AAA large enough, or that will become large enough, to benefit from surgery. In general, adults younger than age 65 and adults of any age who have never smoked are at low risk for AAA and are not likely to benefit from screening. Among men aged 65 to 74, an estimated 500 who have ever smoked—or 1783 who have never smoked—would need to be screened to prevent 1 AAA-related death in the next 5 years. As always, clinicians must individualize recommendations depending on a patient's risk and likelihood of benefit. For example, some clinicians may choose to discuss screening with male nonsmokers nearing age 65 who have a strong first-degree family history of AAA that required surgery.
- The potential benefit of screening for AAA among women aged 65 to 75 is low because of the small number of AAA-related deaths in this population. The majority of deaths from AAA rupture occur in women aged 80 or older. Because there are many competing health risks at this age, any benefit of screening for AAA would be minimal. Individualization of care, however, is still required. For example, a clinician may choose to discuss screening in the unusual circumstance in which a healthy female smoker in her early 70s has a first-degree family history for AAA that required surgery.
- Operative mortality for open surgical repair of an AAA is 4 to 5 percent, and nearly one-third of patients undergoing this surgery have other important complications (e.g., cardiac and pulmonary). Additionally, men having this surgery are at increased risk for impotence.
- Endovascular repair of AAAs (EVAR) is currently being used as an alternative to open surgical repair. Although recent studies have shown a short-term mortality and morbidity benefit of EVAR compared with open surgical repair, the long-term effectiveness of EVAR to reduce AAA rupture and mortality is unknown. The long-term harms of EVAR include late conversion to open repair and aneurysmal rupture. EVAR performed with older-generation devices is reported to have an annual rate of rupture of 1 percent and conversion to open surgical repair of 2 percent. The conversion to open surgical repair is associated with a peri-operative mortality of about 24 percent. The long-term harms of newer generation EVAR devices are yet to be reported.
- For most men, 75 years may be considered an upper age limit for screening. Patients cannot benefit from screening and subsequent surgery unless they have a reasonable life expectancy. The increased presence of comorbidities for people aged 75 and older decreases the likelihood that they will benefit from screening.
- Ultrasonography has a sensitivity of 95 percent and specificity of nearly 100 percent when performed in a setting with adequate quality assurance. The absence of quality assurance is likely to lower test accuracy. Abdominal palpation has poor accuracy and is not an adequate screening test.
- One-time screening to detect an AAA using ultrasonography is sufficient. There is negligible health benefit in re-screening those who have normal aortic diameter on initial screening.
- Open surgical repair for an AAA of at least 5.5 cm leads to an estimated 43-percent reduction in AAA-specific mortality in older men who undergo screening. However, there is no current evidence that screening reduces all-cause mortality in this population.
- In men with intermediate-sized AAAs (4.0-5.4 cm), periodic surveillance offers comparable mortality benefit to routine elective surgery with the benefit of fewer operations. Although there is no evidence to support the effectiveness of any intervention in those with small AAAs (3.0-3.9 cm), there are expert opinion-based recommendations in favor of periodic repeat ultrasonography for these patients.

B. ASPIRIN FOR THE PRIMARY PREVENTION OF CARDIOVASCULAR EVENTS

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) strongly recommends that clinicians discuss aspirin chemoprevention with adults who are at increased risk for coronary heart disease (CHD). Discussions with patients should address both the potential benefits and harms of aspirin therapy. *Rating: A Recommendation.*

CLINICAL CONSIDERATIONS

- Decisions about aspirin therapy should take into account overall risk for coronary heart disease. Risk assessment should include asking about the presence and severity of the following risk factors: age, sex, diabetes, elevated total cholesterol levels, low levels of high-density lipoprotein (HDL) cholesterol, elevated blood pressure, family history (in younger adults), and smoking. Tools that incorporate specific information on multiple risk factors provide more accurate estimation of cardiovascular risk than categorizations based simply on counting the numbers of risk factors (http://www.intmed.mcw.edu/clincalc/heartrisk.html).[1]
- Men older than 40 years, postmenopausal women, and younger people with risk factors for CHD (e.g., hypertension, diabetes, or smoking) are at increased risk for heart disease and may wish to consider aspirin therapy. Table 1 shows how estimates of the type and magnitude of benefits and harms associated with aspirin therapy vary with an individual's underlying risk for coronary heart disease. Although balance of benefits and harms is most favorable in high-risk people (5-year risk

TABLE 1 Estimates of Benefits and Harms of Aspirin Therapy Given for 5 Years to 1000 Individuals with Various Levels of Baseline Risk for Coronary Heart Disease*

Baseline risk for coronary heart disease over 5 years: 1%
Total mortality: No effect
CHD events**: 1-4 avoided
Hemorrhagic strokes***: 0-2 caused
Major gastrointestinal bleeding events****: 2-4 caused
Baseline risk for coronary heart disease over 5 years: 3%
Total mortality: No effect
CHD events**: 4-12 avoided
Hemorrhagic strokes***: 0-2 caused
Major gastrointestinal bleeding events****: 2-4 caused
Baseline risk for coronary heart disease over 5 years: 5%
Total mortality: No effect
CHD events**: 6-20 avoided
Hemorrhagic strokes***: 0-2 caused
Major gastrointestinal bleeding events****: 2-4 caused

*These estimates are based on a relative risk reduction of 28% for coronary heart disease events in aspirin-treated patients. They assume risk reductions do not vary significantly by age.

**Nonfatal acute myocardial infarction and fatal coronary heart disease. Five-year risks of 1%, 3%, and 5% are equivalent to 10-year risks of 2%, 6%, and 10%, respectively.

***Data from secondary prevention trials suggest that increases in hemorrhagic stroke may be offset by reduction in other types of stroke in patients at very high risk for cardiovascular disease (CVD) (greater than or equal to 10% 5-year risk).

****Rates may be 2 to 3 times higher in people older than 70 years.

Source: Hayden M, Pignone M, Phillips C, Mulrow C: Aspirin for the primary prevention of cardiovascular events: A summary of the evidence for the U.S. Preventive Services Task Force, *Annals of Internal Medicine* 136:161-172, 2002.

$>$ 3%), some people at lower risk may consider the potential benefits of aspirin to be sufficient to outweigh the potential harms.

- Discussions about aspirin therapy should focus on potential coronary heart disease benefits, such as prevention of myocardial infarction, and potential harms, such as gastrointestinal and intracranial bleeding. Discussions should take into account individual preferences and risk aversions concerning myocardial infarction, stroke, and gastrointestinal bleeding.
- Although the optimal timing and frequency of discussions related to aspirin therapy are unknown, reasonable options include every 5 years in middle-aged and older people or when other cardiovascular risk factors are detected.
- Most participants in the primary prevention trials of aspirin therapy have been men between 40 and 75 years of age. Current estimates of benefits and harms may not be as reliable for women and older men.
- Although older patients may derive greater benefits because they are at higher risk for CHD and stroke, their risk for bleeding may be higher.
- Uncontrolled hypertension may attenuate the benefits of aspirin in reducing CHD.
- The optimum dose of aspirin for chemoprevention is not known. Primary and secondary prevention trials have demonstrated benefits with a variety of regimens, including 75 mg per day, 100 mg per day, and 325 mg every other day. Doses of approximately 75 mg per day appear as effective as higher doses; whether doses below 75 mg per day are effective has not been established. Enteric-coated or buffered preparations do not clearly reduce adverse gastrointestinal effects of aspirin. Uncontrolled hypertension and concomitant use of other nonsteroidal anti-inflammatory agents or anticoagulants increase risk for serious bleeding.

C. SCREENING FOR CORONARY HEART DISEASE

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine screening with resting electrocardiography (ECG), exercise treadmill test (ETT), or electron-beam computerized tomography (EBCT) scanning for coronary calcium for either the presence of severe coronary artery stenosis (CAS) or the prediction of coronary heart disease (CHD) events in adults at low risk for CHD events. *Rating: D Recommendation.*

The USPSTF found insufficient evidence to recommend for or against routine screening with ECG, ETT, or EBCT scanning for coronary calcium for either the presence of severe CAS or the prediction of CHD events in adults at increased risk for CHD events. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Several factors are associated with a higher risk for CHD events (the major ones are nonfatal myocardial infarction and coronary death), including older age, male gender, high blood pressure, smoking, abnormal lipid levels, diabetes, obesity, and sedentary lifestyle. A person's risk for CHD events can be estimated based on the presence of these factors. Calculators are available to ascertain a person's risk for having a CHD event; for example, a calculator to estimate a person's risk for a CHD event in the next 10 years can be accessed at http://hin.nhlbi.nih.gov/atpiii/calculator.asp?usertype=prof. Although the exact risk factors that constitute each of these categories (low or increased risk) have not been established, younger adults (i.e., men $<$ 50 years and women $<$ 60 years) who have no other risk factors for CHD ($<$ 5%-10% 10-year risk) are considered to be at low risk. Older adults, or younger adults with 1 or more risk factors ($>$ 15%-20% 10-year risk), are considered to be at increased risk.
- Screening with ECG, ETT, and EBCT could potentially reduce CHD events in 2 ways: either by detecting people at high risk for CHD events who could benefit from more aggressive risk factor modification, or by detecting people with existing severe CAS whose life could be prolonged by coronary artery bypass grafting (CABG) surgery. However, the evidence is inadequate to determine the extent to which people detected through screening in either situation would benefit from either type of intervention.
- The consequences of false-positive tests may potentially outweigh the benefits of screening. False-positive tests are common among asymptomatic adults, especially women, and may lead to unnecessary diagnostic testing, over-treatment, and labeling.
- Because the sensitivity of these tests is limited, screening could also result in false-negative results. A negative test does not rule out the presence of severe CAS or a future CHD event.
- For people in certain occupations, such as pilots and heavy equipment operators (for whom sudden incapacitation or sudden death may endanger the safety of others), considerations other than the health benefit to the individual patient may influence the decision to screen for CHD.
- Although some exercise programs initially screen asymptomatic participants with ETT, there is not enough evidence to determine the balance of benefits and harms of this practice.

D. SCREENING FOR LIPID DISORDERS IN ADULTS

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) strongly recommends that clinicians routinely screen men aged 35 years and older and women aged 45 years and older for lipid disorders and treat abnormal lipids in people who are at increased risk for coronary heart disease. *Rating: A Recommendation.*

The USPSTF recommends that clinicians routinely screen younger adults (men aged 20 to 35 years and women aged 20 to 45 years) for lipid disorders if they have other risk factors for cor-

onary heart disease. (See Clinical Considerations for a discussion of risk factors.) *Rating: B Recommendation.*

The USPSTF makes no recommendation for or against routine screening for lipid disorders in younger adults (men aged 20 to 35 years or women aged 20 to 45 years) in the absence of known risk factors for coronary heart disease. *Rating: C Recommendation.*

The USPSTF recommends that screening for lipid disorders include measurement of total cholesterol (TC) and high-density lipoprotein cholesterol (HDL-C). *Rating: B Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against triglyceride measurement as a part of routine screening for lipid disorders. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- TC and HDL-C can be measured on nonfasting or fasting samples.
- Abnormal results should be confirmed by a repeated sample on a separate occasion, and the average of both results should be used for risk assessment. Although measuring both TC and HDL-C is more sensitive and specific for assessing coronary heart disease risk, TC alone is an acceptable screening test if available laboratory services cannot provide reliable measurements of HDL. In conjunction with HDL-C, low-density lipoprotein cholesterol (LDLC) and TC provide comparable information, but measuring LDL-C requires a fasting sample and is more expensive. In patients with elevated risk on screening results, lipoprotein analysis, including fasting triglycerides, may provide information that is useful in choosing optimal treatments.
- Screening is recommended for men aged 20 to 35 years and for women aged 20 to 45 years in the presence of any of the following:
  - Diabetes.
  - A family history of cardiovascular disease before age 50 years in male relatives or age 60 years in female relatives.
  - A family history suggestive of familial hyperlipidemia.
  - Multiple coronary heart disease risk factors (e.g., tobacco use, hypertension).
- The optimal interval for screening is uncertain. On the basis of other guidelines and expert opinion, reasonable options include every 5 years, shorter intervals for people who have lipid levels close to those warranting therapy, and longer intervals for low-risk people who have had low or repeatedly normal lipid levels.
- An age to stop screening is not established. Screening may be appropriate in older people who have never been screened, but repeated screening is less important in older people because lipid levels are less likely to increase after age 65 years.
- Treatment decisions should take into account overall risk of heart disease rather than lipid levels alone. Overall risk assessment should include the presence and severity of the following risk factors: age, gender, diabetes, elevated blood pressure, family history (in younger adults), and smoking. Tools that incorporate specific information on multiple risk factors provide more accurate estimation of cardiovascular risk than categorizations based on counting the numbers of risk factors.[1,2]
- Treatment choices should take into account costs and patient preferences. Drug therapy is usually more effective than diet alone, but choice of treatment should consider overall risk, costs of treatment, and patient preferences. Guidelines for treating high cholesterol are available from the National Cholesterol Education Program of the National Institutes of Health.[3] Although diet therapy is an appropriate initial therapy for most patients, a minority achieve substantial reductions in lipid levels from diet alone; drugs are frequently needed to achieve therapeutic goals, especially for high-risk people. Lipid-lowering treatments should be accompanied by interventions addressing all modifiable risk factors for heart disease, including smoking cessation, treatment of blood pressure, diabetes, and obesity, as well as promotion of a healthy diet and regular physical activity. Long-term adherence to therapies should be emphasized.
- All patients, regardless of lipid levels, should be offered counseling about the benefits of a diet low in saturated fat and high in fruits and vegetables, regular physical activity, avoiding tobacco use, and maintaining a healthy weight.

E. SCREENING FOR PERIPHERAL ARTERIAL DISEASE

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine screening for peripheral arterial disease (PAD). *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- The ankle brachial index, a ratio of Doppler-recorded systolic pressures in the lower and upper extremities, is a simple and accurate noninvasive test for the screening and diagnosis of PAD. The ankle brachial index has demonstrated better accuracy than other methods of screening, including history-taking, questionnaires, and palpation of peripheral pulses. An ankle-brachial index value of less than 0.90 (95% sensitive and specific for angiographic PAD) is strongly associated with limitations in lower extremity functioning and physical activity tolerance.
- Smoking cessation and lipid-lowering agents improve claudication symptoms and lower extremity functioning among patients with symptomatic PAD. Smoking cessation and physical activity training also increase maximal walking distance among men with early PAD. Counseling for smoking cessation, however, should be offered to all patients who smoke, regardless of the presence of PAD. Similarly, physically inactive patients should be counseled to increase their physical activity, regardless of the presence of PAD.

3. INFECTIOUS DISEASES

A. SCREENING FOR ASYMPTOMATIC BACTERIURIA

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) strongly recommends that all pregnant women be screened for asymptomatic bacteriuria using urine culture at 12-16 weeks' gestation. *Rating: A Recommendation.*

The USPSTF recommends against the routine screening of men and nonpregnant women for asymptomatic bacteriuria. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- The screening tests used commonly in the primary care setting (dipstick analysis and direct microscopy) have poor positive and negative predictive value for detecting bacteriuria in asymptomatic persons. Urine culture is the gold standard for detecting asymptomatic bacteriuria but is expensive for routine screening in populations with a low prevalence of this condition. Results from one study done with a new enzymatic urine screening test (Uriscreen™) showed that the test has a sensitivity of 100% and a specificity of 81%.
- Good evidence exists that screening pregnant women for asymptomatic bacteriuria with urine culture (rather than urinalysis) significantly reduces symptomatic urinary tract infections, low birth weight, and preterm delivery. A specimen obtained at 12-16 weeks' gestation will detect approximately 80% of patients with asymptomatic bacteriuria. The optimal frequency of subsequent urine testing during pregnancy is uncertain.

- Good evidence exists that screening individuals other than pregnant women for asymptomatic bacteriuria does not significantly improve clinical outcomes. Results from a study of women with diabetes who were treated for asymptomatic bacteriuria demonstrated no reduction in complications.[1] Although there were short-term results in clearing bacteriuria with antimicrobial therapy, there was no decrease in the number of symptomatic episodes or hospitalizations over the long term. Furthermore, the high rate of recurrence of bacteriuria in those who were screened and treated resulted in a marked increase in the use of antimicrobial agents.

B. SCREENING FOR CHLAMYDIAL INFECTION

Summary of Recommendation

Screen for chlamydial infection in all sexually active nonpregnant young women aged 24 years or younger and for older nonpregnant women who are at increased risk. *Rating: A Recommendation.*

Screen for chlamydial infection in all pregnant women aged 24 years or younger and in older pregnant women who are at increased risk. *Rating: B Recommendation.*

Do not routinely screen for chlamydial infection in women aged 25 years or older, regardless of whether they are pregnant, if they are not at increased risk. *Rating: C Recommendation.*

Current evidence is insufficient to assess the balance of benefits and harms of screening for chlamydial infection for men. *Rating: I Statement.*

CLINICAL CONSIDERATIONS

- Women and adolescents through age 20 years are at highest risk for chlamydial infection, but most reported data indicate that infection is prevalent among women aged 20-24.
- Age is the most important risk marker. Other patient characteristics associated with a higher prevalence of infection include being unmarried, African-American race, having a prior history of sexually transmitted disease (STD), having new or multiple sexual partners, having cervical ectopy, and using barrier contraceptives inconsistently. Individual risk depends on the number of risk markers and local prevalence of the disease. Specific risk-based screening protocols need to be tested at the local level.
- Clinicians should consider the characteristics of the communities they serve in determining appropriate screening strategies for their patient population.
- More targeted screening may be indicated in specific settings as better prevalence data become available. Prevalence of chlamydial infection varies widely among communities and patient populations. Knowledge of the patient population is the best guide to developing a screening strategy. Local public health authorities can be a source of valuable information.
- The optimal interval for screening is uncertain. For women with a previous negative screening test, the interval for rescreening should take into account changes in sexual partners. If there is evidence that a woman is at low risk for infection (e.g., in a mutually monogamous relationship with a previous history of negative screening tests for chlamydial infection), it may not be necessary to screen frequently. Rescreening at 6 to 12 months may be appropriate for previously infected women because of high rates of reinfection.
- The optimal timing of screening in pregnancy is also uncertain. Screening early in pregnancy provides greater opportunities to improve pregnancy outcomes, including low birth weight and premature delivery; however, screening in the third trimester may be more effective at preventing transmission of chlamydial infection to the infant during birth. The incremental benefit of repeated screening is unknown.
- Screening high-risk young men is a clinical option. Until the advent of urine-based screening tests, routine screening of men was rarely performed. As a result, very little evidence regarding the efficacy of screening in men in reducing infection among women exists. Trials are underway to assess the effectiveness of screening asymptomatic men.
- The choice of specific screening technique is left to clinical judgment. Choice of test will depend on issues of cost, convenience, and feasibility, which may vary in different settings. Although specificity is high with most approved tests, false-positive results can occur with all non-culture tests and rarely with culture tests. Subsequent to initial release of this recommendation, the Centers for Disease Control and Prevention (CDC) released laboratory guidelines that outline the advantages and disadvantages of available tests. These guidelines are available at http://www.cdc.gov/STD/LabGuidelines.
- Partners of infected individuals should be tested and treated if infected or treated presumptively.
- Clinicians should remain alert for findings suggestive of chlamydial infection during pelvic examination of asymptomatic women (e.g., discharge, cervical erythema, and cervical friability).
- Clinicians should be sensitive to the potential effect of diagnosing a sexually transmitted disease on a couple. To prevent false-positive results, confirmatory testing may be appropriate in settings with low population prevalence.

C. SCREENING FOR GENITAL HERPES

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine serological screening for herpes simplex virus (HSV) in asymptomatic pregnant women at any time during pregnancy to prevent neonatal HSV infection. *Rating: D Recommendation.*

The USPSTF recommends against routine serological screening for HSV in asymptomatic adolescents and adults. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- Serological screening tests for genital herpes can detect prior infection with HSV in asymptomatic persons, and new type-specific serological tests can differentiate between HSV-1 and HSV-2 exposure (these tests cannot differentiate between oral vs. genital herpes exposure); however, given the natural history of genital herpes, there is limited evidence to guide clinical intervention in those asymptomatic persons who have positive serological test results. False-positive test results may lead to labeling and psychological stress without any potential benefit to patients. Negative test results (both false-negative and true-negative results) may provide false reassurance to continue high-risk sexual behaviors.
- There is new, good-quality evidence demonstrating that systemic antiviral therapy effectively reduces viral shedding and recurrences of genital herpes in adolescents and adults with a history of recurrent genital herpes. There are multiple efficacious regimens that may be used to prevent the recurrence of clinical genital herpes.
- The USPSTF did not examine the evidence for the effectiveness of counseling to avoid high-risk sexual behavior in persons with a history of genital herpes to prevent transmission to discordant partners, or for the primary prevention of genital herpes in persons not infected with HSV. There are known health benefits of avoiding high-risk sexual behavior, including prevention of sexually transmitted infections (STIs) and HIV infection.
- Primary HSV infection during pregnancy presents the greatest risk for transmitting infection to the newborn. The fact that women with primary HSV infection are initially seronegative limits the usefulness of screening with antibody tests. The USPSTF did not find any studies testing the use of antibody screening to find and treat seronegative pregnant women (i.e., those at risk for primary HSV infection) prophylactically. However, the number of seronegative pregnant women one would need to treat to theoretically avoid one primary infection would be very high, making the potential benefit small. At the same time, the potential harm to many

low-risk women and fetuses from the side effects of antiviral therapy may be great.
- There is fair evidence that antiviral therapy in late pregnancy can reduce HSV recurrence and viral shedding at delivery in women with recurrent HSV infection; however, there is currently no evidence that antiviral use in women with a history of HSV leads to reduced neonatal infection. Likewise, there is limited information on the benefits of screening women in labor for signs of active genital HSV lesions, and for the performance of cesarean delivery on those with lesions.

D. SCREENING FOR GONORRHEA

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends that clinicians screen all sexually active women, including those who are pregnant, for gonorrhea infection if they are at increased risk for infection (that is, if they are young or have other individual or population risk factors; see Clinical Considerations for further discussion of risk factors). *Rating: B Recommendation.*

The USPSTF found insufficient evidence to recommend for or against routine screening for gonorrhea infection in men at increased risk for infection (see Clinical Considerations for discussion of risk factors). *Rating: I Recommendation.*

The USPSTF recommends against routine screening for gonorrhea infection in men and women who are at low risk for infection (see Clinical Considerations for discussion of risk factors). *Rating: D Recommendation.*

The USPSTF found insufficient evidence to recommend for or against routine screening for gonorrhea infection in pregnant women who are not at increased risk for infection (see Clinical Considerations for discussion of risk factors). *Rating: I Recommendation.*

The USPSTF strongly recommends prophylactic ocular topical medication for all newborns against gonococcal ophthalmia neonatorum. *Rating: A Recommendation.*

CLINICAL CONSIDERATIONS

- Women and men under the age of 25—including sexually active adolescents—are at highest risk for genital gonorrhea infection. Risk factors for gonorrhea include a history of previous gonorrhea infection, other sexually transmitted infections, new or multiple sexual partners, inconsistent condom use, sex work, and drug use. Risk factors for pregnant women are the same as for non-pregnant women. Prevalence of gonorrhea infection varies widely among communities and patient populations. African Americans and men who have sex with men have a higher prevalence of infection than the general population in many communities and settings.
- Individual risk depends on the local epidemiology of disease. Local public health authorities provide guidance to clinicians to help identify populations who are at increased risk in their communities. In communities with a high prevalence of gonorrhea, broader screening of sexually active young people may be warranted, especially in settings serving individuals who are at increased risk. Additionally, clinicians may want to consider other population-based risk factors, including residence in urban communities and communities with high rates of poverty, when making screening decisions. Low community prevalence of gonorrhea infection may justify more targeted screening.
- Screening is recommended at the first prenatal visit for pregnant women who are in a high risk group for gonorrhea infection. For pregnant patients who are at continued risk, and for those who acquire a new risk factor, a second screening should be conducted during the third trimester. The optimal interval for screening in the non-pregnant population is not known.
- Vaginal culture remains an accurate screening test when transport conditions are suitable. Newer screening tests, including nucleic acid amplification tests and nucleic acid hybridization tests, have demonstrated improved sensitivity and comparable specificity when compared with cervical culture. Some newer tests can be used with urine and vaginal swabs, which enables screening when a pelvic examination is not performed.
- Appropriate treatment of gonorrhea infection and administration of prophylactic medication to newborns have been outlined by the Centers for Disease Control and Prevention (CDC) (http://www.cdc.gov/std/treatment/42002TG.htm#Gonococcal). Genital infection in men and women may be treated with a third generation cephalosporin or fluoroquinolone, and pregnant women may be treated with third generation cephalosporins. Because of emerging fluoroquinolone resistance, the CDC issued new treatment guidelines in 2004 recommending that men who have sex with men and those who acquired an infection in California, Hawaii, or Asia not be treated with fluoroquinolone antibiotics. If clinicians have not concurrently screened for chlamydial infection, the CDC recommends presumptive treatment for chlamydia at the time of treatment for gonorrhea. In order to prevent recurrent transmission, partners of infected individuals should be tested and treated if infected, or treated presumptively.
- Gonorrhea is a nationally reportable condition. More complete reporting of gonorrhea cases to public health authorities will permit more accurate estimations of gonorrhea prevalence. Improved information will allow clinicians to screen for gonorrhea in ways that improve the balance between benefits and harms for their patients.
- Research priorities for gonorrhea screening include greater understanding of the benefits of screening men at increased risk, especially men who have sex with men, and the role of reporting on gonorrhea rates and testing priorities.

E. SCREENING FOR HEPATITIS B VIRUS INFECTION

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) strongly recommends screening for hepatitis B virus (HBV) infection in pregnant women at their first prenatal visit. *Rating: A Recommendation.*

The USPSTF recommends against routinely screening the general asymptomatic population for chronic hepatitis B virus infection. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- Routine hepatitis vaccination has had significant impact in reducing the number of new HBV infections per year, with the greatest decline among children and adolescents. Programs that vaccinate health care workers also reduce the transmission of HBV infection.
- Most people who become infected as adults or older children recover fully from HBV infection and develop protective immunity to the virus.
- The main risk factors for HBV infection in the United States include diagnosis with a sexually transmitted disease, intravenous drug use, sexual contact with multiple partners, male homosexual activity, and household contacts of chronically infected persons. However, screening strategies to identify individuals at high risk have poor predictive value, since 30% to 40% of infected individuals do not have any easily identifiable risk factors.
- Important predictors of progressive HBV infection include longer duration of infection and the presence of comorbid conditions such as alcohol abuse, HIV, or other chronic liver disease. Individuals with HBV infection identified through screening may benefit from interventions designed to reduce liver injury from other causes, such as counseling to avoid alcohol abuse and immunization against hepatitis A. However, there is limited evidence on the effectiveness of these interventions.

F. SCREENING FOR HEPATITIS C IN ADULTS

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against routine screening for hepatitis C virus (HCV) infection in asymptomatic adults who are not at increased risk (general population) for infection. *Rating: D Recommendation.*

The USPSTF found insufficient evidence to recommend for or against routine screening for HCV infection in adults at high risk for infection. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Established risk factors for HCV infection include current or past intravenous drug use, transfusion before 1990, dialysis, and being a child of an HCV-infected mother. Surrogate markers, such as high-risk sexual behavior (particularly sex with someone infected with HCV) and the use of illegal drugs, such as cocaine or marijuana, have also been associated with increased risk for HCV infection. The proportion of people who received blood or blood product transfusions before 1990 will continue to decline, and HCV infection will be associated mainly with intravenous drug use and, to some extent, unsafe sexual behaviors.
- Initial testing for HCV infection is typically done by enzyme immunoassay (EIA). In a population with a low prevalence of HCV infection (e.g., 2%), approximately 59% of all positive tests using the third-generation EIA test with 97% specificity would be false positive. As a result, confirmatory testing is recommended with the strip recombinant immunoblot assay (third-generation RIBA).
- Important predictors of progressive HCV infection include older age at acquisition; longer duration of infection; and presence of comorbid conditions, such as alcohol misuse, HIV infection, or other chronic liver disease. Asymptomatic individuals with HCV infection identified through screening may benefit from interventions designed to reduce liver injury from other causes, such as counseling to avoid alcohol misuse and immunization against hepatitis A and hepatitis B. However, there is limited evidence of the effectiveness of these interventions.

G. SCREENING FOR SYPHILIS INFECTION

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) strongly recommends that clinicians screen persons at increased risk for syphilis infection. *Rating: A Recommendation.*

The USPSTF strongly recommends that clinicians screen all pregnant women for syphilis infection. *Rating: A Recommendation.*

The USPSTF recommends against routine screening of asymptomatic persons who are not at increased risk for syphilis infection. *Rating: D Recommendation.*

CLINICAL CONSIDERATIONS

- Populations at increased risk for syphilis infection (as determined by incident rates) include men who have sex with men and engage in high-risk sexual behavior, commercial sex workers, persons who exchange sex for drugs, and those in adult correctional facilities. There is no evidence to support an optimal screening frequency in this population. Clinicians should consider the characteristics of the communities they serve in determining appropriate screening strategies. Prevalence of syphilis infection varies widely among communities and patient populations. For example, the prevalence of syphilis infection differs by region (the prevalence of infection is higher in the southern U.S. and in some metropolitan areas than it is in the U.S. as a whole) and by ethnicity (the prevalence of syphilis infection is higher in Hispanic and African American populations than it is in the white population).
- Persons diagnosed with other sexually transmitted diseases (STDs) (i.e., chlamydia, gonorrhea, genital herpes simplex, human papilloma virus, and HIV) may be more likely than others to engage in high-risk behavior, placing them at increased risk for syphilis; however, there is no evidence that supports the routine screening of individuals diagnosed with other STDs for syphilis infection. Clinicians should use clinical judgment to individualize screening for syphilis infection based on local prevalence and other risk factors (see above).
- Nontreponemal tests commonly used for initial screening are the Venereal Disease Research Laboratory (VDRL) or Rapid Plasma Reagin (RPR), followed by a confirmatory fluorescent treponemal antibody absorbed (FTA-ABS) or *T. pallidum* particle agglutination (TP-PA). The optimal screening interval in average- and high-risk persons has not been determined.
- All pregnant women should be tested at their first prenatal visit. For women in high-risk groups, repeat serologic testing may be necessary in the third trimester and at delivery. Follow-up serologic tests should be obtained to document decline initially after treatment. These follow-up tests should be performed using the same nontreponemal test initially used to document infections (e.g., VDRL or RPR) to ensure comparability.

4. INJURY AND VIOLENCE

A. SCREENING FOR FAMILY AND INTIMATE PARTNER VIOLENCE

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) found insufficient evidence to recommend for or against routine screening of parents or guardians for the physical abuse or neglect of children, of women for intimate partner violence, or of older adults or their caregivers for elder abuse. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- The USPSTF did not review the evidence for the effectiveness of case-finding tools; however, all clinicians examining children and adults should be alert to physical and behavioral signs and symptoms associated with abuse or neglect. Patients in whom abuse is suspected should receive proper documentation of the incident and physical findings (e.g., photographs, body maps); treatment for physical injuries; arrangements for skilled counseling by a mental health professional; and the telephone numbers of local crisis centers, shelters, and protective service agencies.
- Victims of family violence are primarily children, female spouses/intimate partners, and older adults. Numerous risk factors for family violence have been identified, although some may be confounded by socioeconomic factors. Factors associated with child abuse or neglect include low income status, low maternal education, non-white race, large family size, young maternal age, single-parent household, parental psychiatric disturbances, and presence of a stepfather. Factors associated with intimate partner violence include young age, low income status, pregnancy, mental health problems, alcohol or substance use by victims or perpetrators, separated or divorced status, and history of childhood sexual and/or physical abuse. Factors associated with the abuse of older adults include increasing age, nonwhite race, low income status, functional impairment, cognitive disability, substance use, poor emotional state, low self-esteem, cohabitation, and lack of social support.
- Several instruments to screen parents for child abuse have been studied, but their ability to predict child abuse or neglect is limited. Instruments to screen for intimate partner violence have also been developed, and although some have demonstrated good internal consistency (e.g., the HITS [Hurt, Insulted, Threatened, Screamed at] instrument, the Partner Abuse Interview, and the Women's Experience with Battering [WEB] Scale), none have been validated against measurable outcomes. Only a few screening instruments (the Caregiver Abuse Screen [CASE] and the Hwalek-Sengstock Elder Abuse Screening Test [HSEAST]) have been developed to identify potential older victims of abuse or their abusive caretakers. Both of these tools correlated well with previously validated instruments when administered in the community, but have not been tested in the primary care clinical setting.[1]
- Home visit programs directed at high-risk mothers (identified on the basis of sociodemographic risk factors) have improved developmental outcomes and decreased the incidence of child abuse and neglect, as well as decreased rates of maternal criminal activity and drug use.

5. MENTAL HEALTH CONDITIONS AND SUBSTANCE ABUSE

A. SCREENING AND BEHAVIORAL COUNSELING INTERVENTIONS IN PRIMARY CARE TO REDUCE ALCOHOL MISUSE

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends screening and behavioral counseling interventions to reduce alcohol misuse (go to Clinical Considerations) by adults, including pregnant women, in primary care settings. *Rating: B Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against screening and behavioral counseling interventions to prevent or reduce alcohol misuse by adolescents in primary care settings. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Alcohol misuse includes "risky/hazardous" and "harmful" drinking that places individuals at risk for future problems. "Risky" or "hazardous" drinking has been defined in the United States as more than 7 drinks per week or more than 3 drinks per occasion for women, and more than 14 drinks per week or more than 4 drinks per occasion for men. "Harmful drinking" describes persons who are currently experiencing physical, social, or psychological harm from alcohol use but do not meet criteria for dependence.[1,2] Alcohol abuse and dependence are associated with repeated negative physical, psychological, and social effects from alcohol.[3] The USPSTF did not evaluate the effectiveness of interventions for alcohol dependence because the benefits of these interventions are well established and referral or specialty treatment is recommended for those meeting the diagnostic criteria for dependence.
- Light to moderate alcohol consumption in middle-aged or older adults has been associated with some health benefits, such as reduced risk for coronary heart disease.[4] Moderate drinking has been defined as 2 standard drinks (e.g., 12 ounces of beer) or less per day for men and 1 drink or less per day for women and persons older than 65,[5] but recent data suggest comparable benefits from as little as 1 drink 3 to 4 times a week.[6]
- The Alcohol Use Disorders Identification Test (AUDIT) is the most studied screening tool for detecting alcohol-related problems in primary care settings. It is sensitive for detecting alcohol misuse and abuse or dependence and can be used alone or embedded in broader health risk or lifestyle assessments.[7,8] The 4-item CAGE (feeling the need to Cut down, Annoyed by criticism, Guilty about drinking, and need for an Eye-opener in the morning) is the most popular screening test for detecting alcohol abuse or dependence in primary care.[9] The TWEAK, a 5-item scale, and the T-ACE are designed to screen pregnant women for alcohol misuse. They detect lower levels of alcohol consumption that may pose risks during pregnancy.[10] Clinicians can choose screening strategies that are appropriate for their clinical population and setting.[8,11-14] Screening tools are available at the National Institute on Alcohol Abuse and Alcoholism website: http://www.niaaa.nih.gov/.
- Effective interventions to reduce alcohol misuse include an initial counseling session of about 15 minutes, feedback, advice, and goal-setting. Most also include further assistance and follow-up. Multicontact interventions for patients ranging widely in age (12-75 years) are shown to reduce mean alcohol consumption by 3 to 9 drinks per week, with effects lasting up to 6 to 12 months after the intervention. They can be delivered wholly or in part in the primary care setting, and by one or more members of the health care team, including physician and nonphysician practitioners. Resources that help clinicians deliver effective interventions include brief provider training or access to specially trained primary care practitioners or health educators, and the presence of office-level systems supports (prompts, reminders, counseling algorithms, and patient education materials).
- Primary care screening and behavioral counseling interventions for alcohol misuse can be described with reference to the 5-As behavioral counseling framework: assess alcohol consumption with a brief screening tool followed by clinical assessment as needed; advise patients to reduce alcohol consumption to moderate levels; agree on individual goals for reducing alcohol use or abstinence (if indicated); assist patients with acquiring the motivations, self-help skills, or supports needed for behavior change; and arrange follow-up support and repeated counseling, including referring dependent drinkers for specialty treatment.[15] Common practices that complement this framework include motivational interviewing,[16] the 5 Rs used to treat tobacco use,[17] and assessing readiness to change.[18]
- The optimal interval for screening and intervention is unknown. Patients with past alcohol problems, young adults, and other high-risk groups (e.g., smokers) may benefit most from frequent screening.
- All pregnant women and women contemplating pregnancy should be informed of the harmful effects of alcohol on the fetus. Safe levels of alcohol consumption during pregnancy are not known; therefore, pregnant women are advised to abstain from drinking alcohol. More research into the efficacy of primary care screening and behavioral intervention for alcohol misuse among pregnant women is needed.
- The benefits of behavioral intervention for preventing or reducing alcohol misuse in adolescents are not known. The CRAFFT questionnaire was recently validated for screening adolescents for substance abuse in the primary care setting.[19] The benefits of screening this population will need to be evaluated as more effective interventions become available in the primary care setting.

B. SCREENING FOR DEMENTIA

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against routine screening for dementia in older adults. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- The Mini-Mental Status Examination (MMSE) is the best-studied instrument for screening for cognitive impairment. When the MMSE is used to screen unselected patients, the predictive value of a positive result is only fair. The accuracy of the MMSE depends upon a person's age and educational level: using an arbitrary cut-point may potentially lead to more false-positives among older people with lower educational levels, and more false-negatives among younger people with higher educational levels. Tests that assess functional limitations rather than cognitive impairment, such as the Functional Activities Questionnaire (FAQ), can detect dementia with sensitivity and specificity comparable to that of the MMSE.
- Early recognition of cognitive impairment, in addition to helping make diagnostic and treatment decisions, allows clinicians to anticipate problems the patients may have in understanding and adhering to recommended therapy. This information may also be useful to the patient's caregiver(s) and family member(s) in helping to anticipate and plan for future problems that may develop as a result of progression of cognitive impairment.
- Although current evidence does not support routine screening of patients in whom cognitive impairment is not otherwise suspected, clinicians should assess cognitive function whenever cognitive impairment or deterioration is suspected, based on direct observation, patient report, or concerns raised by family members, friends, or caretakers.

C. SCREENING FOR DEPRESSION

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends screening adults for depression in clinical practices that have systems in place to assure accurate diagnosis, effective treatment, and follow-up. *Rating: B Recommendation.*

The USPSTF concludes the evidence is insufficient to recommend for or against routine screening of children or adolescents for depression. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Many formal screening tools are available (e.g., the Zung Self-Assessment Depression Scale, Beck Depression Inventory, General Health Questionnaire [GHQ], Center for Epidemiologic Study Depression Scale [CES-D]).[1] Asking 2 simple questions about mood and anhedonia ("Over the past 2 weeks, have you felt down, depressed, or hopeless?" and "Over the past 2 weeks, have you felt little interest or pleasure in doing things?") may be as effective as using longer instruments.[2] There is little evidence to recommend one screening method over another, so clinicians can choose the method that best fits their personal preference, the patient population served, and the practice setting.
- All positive screening tests should trigger full diagnostic interviews that use standard diagnostic criteria (i.e., those from the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* [DSM-IV]) to determine the presence or absence of specific depressive disorders, such as major depression and/or dysthymia.[3] The severity of depression and comorbid psychological problems (e.g., anxiety, panic attacks, or substance abuse) should be addressed.
- Many risk factors for depression (e.g., female sex, family history of depression, unemployment, and chronic disease) are common, but the presence of risk factors alone cannot distinguish depressed from nondepressed patients.
- The optimal interval for screening is unknown. Recurrent screening may be most productive in patients with a history of depression, unexplained somatic symptoms, comorbid psychological conditions (e.g., panic disorder or generalized anxiety), substance abuse, or chronic pain.
- Clinical practices that screen for depression should have systems in place to ensure that positive screening results are followed by accurate diagnosis, effective treatment, and careful follow-up. Benefits from screening are unlikely to be realized unless such systems are functioning well.
- Treatment may include antidepressants or specific psychotherapeutic approaches (e.g., cognitive behavioral therapy or brief psychosocial counseling), alone or in combination.
- The benefits of routinely screening children and adolescents for depression are not known. The existing literature suggests that screening tests perform reasonably well in adolescents and that treatments are effective, but the clinical impact of routine depression screening has not been studied in pediatric populations in primary care settings. Clinicians should remain alert for possible signs of depression in younger patients. The predictive value of positive screening tests is lower in children and adolescents than in adults, and research on the effectiveness of primary care-based interventions for depression in this age group is limited.

D. SCREENING FOR SUICIDE RISK

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against routine screening by primary care clinicians to detect suicide risk in the general population. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- The strongest risk factors for attempted suicide include mood disorders or other mental disorders, comorbid substance abuse disorders, history of deliberate self-harm (DSH), and a history of suicide attempts. DSH refers to intentionally initiated acts of self-harm with a non-fatal outcome (including self-poisoning and self-injury). Suicide risk is assessed along a continuum ranging from suicidal ideation alone (relatively less severe) to suicidal ideation with a plan (more severe). Suicidal ideation with a specific plan of action is associated with a significant risk for attempted suicide.
- Screening instruments are commonly used in specialty clinics and mental health settings. The test characteristics of most commonly-used screening instruments (Scale for Suicide Ideation [SSI], Scale for Suicide Ideation-Worst [SSI-W], and the Suicidal Ideation Questionnaire [SIQ]) have not been validated to assess suicide risk in primary care settings. There has been limited testing of the Symptom-Driven Diagnostic System for Primary Care (SDDS-PC) screening instrument in a primary care setting.

6. COUNSELING TO PREVENT TOBACCO USE AND TOBACCO-CAUSED DISEASE

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) strongly recommends that clinicians screen all adults for tobacco use and provide tobacco cessation interventions for those who use tobacco products. *Rating: A Recommendation.*

The USPSTF strongly recommends that clinicians screen all pregnant women for tobacco use and provide augmented pregnancy-tailored counseling to those who smoke. *Rating: A Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against routine screening for tobacco use or interventions to prevent and treat tobacco use and dependence among children or adolescents. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Brief tobacco cessation counseling interventions, including screening, brief counseling (3 minutes or less), and/or pharmacotherapy, have proven to increase tobacco abstinence rates, although there is a dose-response relationship between quit rates and the intensity of counseling. Effective interventions may be delivered by a variety of primary care clinicians.
- The 5-A behavioral counseling framework provides a useful strategy for engaging patients in smoking cessation discussions:
  1. **Ask** about tobacco use.
  2. **Advise** to quit through clear personalized messages.
  3. **Assess** willingness to quit.
  4. **Assist** to quit.
  5. **Arrange** follow-up and support.

  Helpful aspects of counseling include providing problem-solving guidance for smokers to develop a plan to quit and to overcome common barriers to quitting and providing social support within and outside of treatment. Common practices that complement this framework include motivational interviewing, the 5-R's used to treat tobacco use (*relevance, risks, rewards, roadblocks, repetition*), assessing readiness to change, and more intensive counseling and/or referrals for quitters needing extra help.[1-3] Telephone "quit lines" have also been found to be an effective adjunct to counseling or medical therapy.[4]
- Clinics that implement screening systems designed to regularly identify and document a patient's tobacco use status increased their rates of clinician intervention, although there is limited evidence for the impact of screening systems on tobacco cessation rates.[5]
- FDA-approved pharmacotherapy that has been identified as safe and effective for treating tobacco dependence includes several forms of nicotine replacement therapy (i.e., nicotine gum, nicotine transdermal patches, nicotine inhaler, and nicotine nasal spray) and sustained-release bupropion. Other medications, including clonidine and nortriptyline, have been found to be efficacious and may be considered.
- Augmented pregnancy-tailored counseling (e.g., 5-15 minutes) and self-help materials are recommended for pregnant smokers, as brief interventions are less effective in this population. There is limited evidence to evaluate the safety or efficacy of pharmacotherapy during pregnancy. Tobacco cessation at any point during pregnancy can yield important health benefits for the mother and the baby, but there are limited data about the optimal timing or frequency of counseling interventions during pregnancy.
- There is little evidence addressing the effectiveness of screening and counseling children or adolescents to prevent the initiation of tobacco use and to promote its cessation in a primary care setting, but clinicians may use their discretion in conducting tobacco-related discussions with this population, since the majority of adult smokers begin tobacco use as children or adolescents.

7. METABOLIC, NUTRITIONAL, AND ENDOCRINE CONDITIONS

A. BEHAVIORAL COUNSELING IN PRIMARY CARE TO PROMOTE A HEALTHY DIET

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against routine behavioral counseling to promote a healthy diet in unselected patients in primary care settings. *Rating: I Recommendation.*

The USPSTF recommends intensive behavioral dietary counseling for adult patients with hyperlipidemia and other known risk factors for cardiovascular and diet-related chronic disease. Intensive counseling can be delivered by primary care clinicians or by referral to other specialists, such as nutritionists or dietitians. *Rating: B Recommendation.*

CLINICAL CONSIDERATIONS

- Several brief dietary assessment questionnaires have been validated for use in the primary care setting.[1,2] These instruments can identify dietary counseling needs, guide interventions, and monitor changes in patients' dietary patterns. However, these instruments are susceptible to the bias of the respondent. Therefore, when used to evaluate the efficacy of counseling, efforts to verify self-reported information are recommended since patients receiving dietary interventions may be more likely to report positive changes in dietary behavior than control patients.[3-6]
- Effective interventions combine nutrition education with behaviorally-oriented counseling to help patients acquire the skills, motivation, and support needed to alter their daily eating patterns and food preparation practices. Examples of behaviorally-oriented counseling interventions include teaching self monitoring, training to overcome common barriers to selecting a healthy diet, helping patients to set their own goals, providing guidance in shopping and food preparation, role playing, and arranging for intra-treatment social support. In general, these interventions can be described with reference to the 5-A behavioral counseling framework.[7]
  1. **Assess** dietary practices and related risk factors.
  2. **Advise** to change dietary practices.
  3. **Agree** on individual diet change goals.
  4. **Assist** to change dietary practices or address motivational barriers.
  5. **Arrange** regular follow-up and support or refer to more intensive behavioral nutritional counseling (e.g., medical nutrition therapy) if needed.
- Two approaches appear promising for the general population of adult patients in primary care settings:
  1. Medium-intensity face-to-face dietary counseling (2 to 3 group or individual sessions) delivered by a dietitian or nutritionist or by a specially trained primary care physician or nurse practitioner.
  2. Lower-intensity interventions that involve 5 minutes or less of primary care provider counseling supplemented by patient self-help

materials, telephone counseling, or other interactive health communications. However, more research is needed to assess the long-term efficacy of these treatments and the balance of benefits and harms.

- The largest effect of dietary counseling in asymptomatic adults has been observed with more intensive interventions (multiple sessions lasting 30 minutes or longer) among patients with hyperlipidemia or hypertension, and among others at increased risk for diet-related chronic disease. Effective interventions include individual or group counseling delivered by nutritionists, dietitians, or specially trained primary care practitioners or health educators in the primary care setting or in other clinical settings by referral. Most studies of these interventions have enrolled selected patients, many of whom had known diet-related risk factors such as hyperlipidemia or hypertension. Similar approaches may be effective with unselected adult patients, but adherence to dietary advice may be lower, and health benefits smaller, than in patients who have been told they are at higher risk for diet-related chronic disease.[8]
- Office-level systems supports (prompts, reminders, and counseling algorithms) have been found to significantly improve the delivery of appropriate dietary counseling by primary care clinicians.[9-11]
- Possible harms of dietary counseling have not been well defined or measured. Some have raised concerns that if patients focus only on reducing total fat intake without attention to reducing caloric intake, an increase in carbohydrate intake (e.g., reduced-fat or low-fat food products) may lead to weight gain, elevated triglyceride levels, or insulin resistance. Nationally, obesity rates have increased despite declining fat consumption, but studies did not consistently examine effects of counseling on outcomes such as caloric intake and weight.
- Little is known about effective dietary counseling for children or adolescents in the primary care setting. Most studies of nutritional interventions for children and adolescents have focused on nonclinical settings (such as schools) or have used physiologic outcomes such as cholesterol or weight rather than more comprehensive measures of a healthy diet.[12,13]

B. HORMONE THERAPY FOR THE PREVENTION OF CHRONIC CONDITIONS IN POSTMENOPAUSAL WOMEN

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends against the routine use of combined estrogen and progestin for the prevention of chronic conditions in postmenopausal women. *Rating: D recommendation.*

The USPSTF recommends against the routine use of unopposed estrogen for the prevention of chronic conditions in postmenopausal women who have had a hysterectomy. *Rating: D recommendation.*

CLINICAL CONSIDERATIONS

- The balance of benefits and harms for a woman will be influenced by her personal preferences, her risks for specific chronic diseases, and the presence of menopausal symptoms. A shared decision making approach to preventing chronic diseases in perimenopausal and postmenopausal women involves consideration of individual risk factors and preferences in selecting effective interventions for reducing the risks for fracture, heart disease, and cancer. See other USPSTF recommendations for prevention of chronic diseases (screening for osteoporosis, high blood pressure, lipid disorders, breast cancer, and colorectal cancer; and counseling to prevent tobacco use) available at http://www.preventiveservices.ahrq.gov.
- The USPSTF did not consider the use of hormone therapy for the management of menopausal symptoms, which is the subject of recommendations by other expert groups. Women and their clinicians should discuss the balance of risks and benefits before deciding to initiate or continue hormone therapy for menopausal symptoms. For example, for combined estrogen and progestin, some risks (such as the risks for venous thromboembolism, coronary heart disease [CHD], and stroke) arise within the first 1 to 2 years of therapy, and other risks (such as the risk for breast cancer) appear to increase with longer-term hormone therapy. The populations of women using hormone therapy for symptom relief may differ from those who would use hormone therapy for prevention of chronic disease (e.g., age differences). Other expert groups have recommended that women who decide to take hormone therapy to relieve menopausal symptoms use the lowest effective dose for the shortest possible time.
- Although estrogen alone or in combination with progestin reduces the risk for fractures in women, other effective medications (e.g., bisphosphonates and calcitonin) are available for treating women with low bone density to prevent fractures. The role of chemopreventive agents in preventing fractures in women without low bone density is unclear. The USPSTF addressed screening for osteoporosis in postmenopausal women in 2002.[1]
- Unopposed estrogen increases the risk for endometrial cancer in women who have an intact uterus. Clinicians should use a shared decision making approach when discussing the possibility of using unopposed estrogen in women who have not had a hysterectomy.[2]

C. SCREENING FOR OBESITY IN ADULTS

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends that clinicians screen all adult patients for obesity and offer intensive counseling and behavioral interventions to promote sustained weight loss for obese adults. *Rating: B Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against the use of moderate- or low-intensity counseling together with behavioral interventions to promote sustained weight loss in obese adults. *Rating: I Recommendation.*

The USPSTF concludes that the evidence is insufficient to recommend for or against the use of counseling of any intensity and behavioral interventions to promote sustained weight loss in overweight adults. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- A number of techniques, such as bioelectrical impedance, dual-energy x-ray absorptiometry, and total body water can measure body fat, but it is impractical to use them routinely. Body mass index (BMI), which is simply weight adjusted for height, is a more practical and widely-used method to screen for obesity. Increased BMI is associated with an increase in adverse health effects. Central adiposity increases the risk for cardiovascular and other diseases independent of obesity. Clinicians may use the waist circumference as a measure of central adiposity. Men with waist circumferences greater than 102 cm (> 40 inches) and women with waist circumferences greater than 88 cm (> 35 inches) are at increased risk for cardiovascular disease. The waist circumference thresholds are not reliable for patients with a BMI greater than 35.
- Expert committees have issued guidelines defining overweight and obesity based on BMI. Persons with a BMI between 25 and 29.9 are overweight and those with a BMI of 30 and above are obese. There are 3 classes of obesity: class I (BMI 30-34.9), class II (BMI 35-39.9), and class III (BMI 40 and above). BMI is calculated either as weight in pounds divided by height in inches squared multiplied by 703, or as weight in kilograms divided by height in meters squared. The National Institutes of Health (NIH) provides a BMI calculator at http://www.nhlbisupport.com/bmi/ and a table at www.nhlbi.nih.gov/guidelines/obesity/bmi_tbl.htm.
- The most effective interventions combine nutrition education and diet and exercise counseling with behavioral strategies to help patients acquire the skills and supports needed to change eating patterns and to become physically active. The 5-A framework (Assess, Advise, Agree, Assist, and Arrange) has been used in behavioral counseling interventions such as smoking cessation and may be a useful tool to help clinicians guide interventions for weight loss. Initial interventions paired with maintenance interventions help ensure that weight loss will be sustained over time.
- It is advisable to refer obese patients to programs that offer intensive counseling and behavioral interventions for optimal weight loss. The USPSTF defined intensity of counseling by the frequency of the intervention. A high-intensity intervention is more than 1 person-to-person (individual or group) session per month for at least the first 3 months of the intervention. A medium-intensity intervention is a monthly intervention, and anything less frequent is a low-intensity intervention. There are limited data on the best place for these interventions to occur and on the composition of the multidisciplinary team that should deliver high-intensity interventions.
- The USPSTF concluded that the evidence on the effectiveness of interventions with obese people may not be generalizable to adults who are overweight but not obese. The evidence for the effectiveness of interventions for weight loss among overweight adults, compared with obese adults, is limited.
- Orlistat and sibutramine, approved for weight loss by the Food and Drug Administration, can produce modest weight loss (2.6-4.8 kg) that can be sustained for at least 2 years if the medication is continued. The adverse effects of orlistat include fecal urgency, oily spotting, and flatulence; the adverse effects of sibutramine include an increase in blood pressure and heart rate. There are no data on the long-term (longer than 2 years) benefits or adverse effects of these drugs. Experts recommend that pharmacological treatment of obesity be used only as part of a program that also includes lifestyle modification interventions, such as intensive diet and/or exercise counseling and behavioral interventions.
- There is fair to good evidence to suggest that surgical interventions such as gastric bypass, vertical banded gastroplasty, and adjustable gastric banding can produce substantial weight loss (28 to > 40 kg) in patients with class III obesity. Clinical guidelines developed by the National Heart, Lung, and Blood Institute (NHLBI) Expert Panel on the identification, evaluation, and treatment of overweight and obesity in adults recommend that these procedures be reserved for patients with class III obesity and for patients with class II obesity who have at least 1 other obesity-related illness. The postoperative mortality rate for these procedures is 0.2 percent. Other complications include wound infection, re-operation, vitamin deficiency, diarrhea, and hemorrhage. Re-operation may be necessary in up to 25 percent of patients. Patients should receive a psychological evaluation prior to undergoing these procedures. The long-term health effects of surgery for obesity are not well characterized.
- The data supporting the effectiveness of interventions to promote weight loss are derived mostly from women, especially white women. The effectiveness of the interventions is less well established in other populations, including the elderly. The USPSTF believes that, although the data are limited, these interventions may be used with obese men, physiologically mature older adolescents, and diverse populations, taking into account cultural and other individual factors.

D. BEHAVIORAL COUNSELING IN PRIMARY CARE TO PROMOTE PHYSICAL ACTIVITY

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against behavioral counseling in primary care settings to promote physical activity. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Regular physical activity helps prevent cardiovascular disease, hypertension, type 2 diabetes, obesity, and osteoporosis. It may also decrease all-cause morbidity and lengthen life-span.[1]
- Benefits of physical activity are seen at even modest levels of activity, such as walking or bicycling 30 minutes per day on most days of the week. Benefits increase with increasing levels of activity.[2]
- Whether routine counseling and follow-up by primary care physicians results in increased physical activity among their adult patients is unclear. Existing studies limit the conclusions that can be drawn about efficacy, effectiveness, and feasibility of primary care physical activity counseling. Most studies have tested brief, minimal, and low-intensity primary care interventions, such as 3- to 5-minute counseling sessions in the context of a routine clinical visit.
- Multi-component interventions combining provider advice with behavioral interventions to facilitate and reinforce healthy levels of physical activity appear the most promising. Such interventions often include patient goal setting, written exercise prescriptions, individually tailored physical activity regimens, and mailed or telephone follow-up assistance provided by specially trained staff. Linking primary care patients to community-based physical activity and fitness programs may enhance the effectiveness of primary care clinician counseling.[3]
- Potential harms of physical activity counseling have not been well defined or studied. They may include muscle and fall-related injuries or cardiovascular events.[4] It is unclear whether more extensive patient screening, certain types of physical activity (e.g., moderate vs vigorous exercise), more gradual increases in exercise, or more intensive counseling and follow-up monitoring will decrease the likelihood of injuries related to physical activity. Existing studies provide insufficient evidence regarding the potential harms of various activity protocols, such as moderate compared with vigorous exercise.

E. SCREENING FOR THYROID DISEASE

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes the evidence is insufficient to recommend for or against routine screening for thyroid disease in adults. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Subclinical thyroid dysfunction is defined as an abnormal biochemical measurement of thyroid hormones without any specific clinical signs or symptoms of thyroid disease and no history of thyroid dysfunction or therapy. This includes individuals who have mildly elevated TSH and normal thyroxine (T4) and triiodothyronine (T3) levels (subclinical hypothyroidism), or low TSH and normal T4 and T3 levels (subclinical hyperthyroidism). Individuals with symptoms of thyroid dysfunction, or those with a history of thyroid disease or treatment, are excluded from this definition and are not the subject of these recommendations.
- When used to confirm suspected thyroid disease in patients referred to a specialty endocrine clinic, TSH has a high sensitivity (98%) and specificity (92%). When used for screening primary care populations, the positive predictive value (PPV) of TSH in detecting thyroid disease is low; further, the interpretation of a positive test result is often complicated by an underlying illness or by frailty of the individual. In general, values for serum TSH below 0.1 mU/L are considered low and values above 6.5 mU/L are considered elevated.
- Clinicians should be aware of subtle signs of thyroid dysfunction, particularly among those at high risk. People at higher risk for thyroid dysfunction include the elderly, postpartum women, those with high levels of radiation exposure (>20 mGy), and patients with Down syndrome. Evaluating for symptoms of hypothyroidism is difficult in patients with Down syndrome because some symptoms and signs (e.g., slow speech, thick tongue, and slow mentation) are typical findings in both conditions.
- Subclinical hyperthyroidism has been associated with atrial fibrillation, dementia, and, less clearly, with osteoporosis. However, progression from subclinical to clinical disease in patients without a history of thyroid disease is not clearly established.
- Subclinical hypothyroidism is associated with poor obstetric outcomes and poor cognitive development in children. Evidence for dyslipidemia, atherosclerosis, and decreased quality of life in adults with subclinical hypothyroidism in the general population is inconsistent and less convincing.

F. SCREENING FOR TYPE 2 DIABETES MELLITUS IN ADULTS

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against routinely screening asymptomatic adults for type 2 diabetes, impaired glucose tolerance, or impaired fasting glucose. *Rating: I Recommendation.*

The USPSTF recommends screening for type 2 diabetes in adults with hypertension or hyperlipidemia. *Rating: B Recommendation.*

CLINICAL CONSIDERATIONS

- In the absence of evidence of direct benefits of routine screening for type 2 diabetes, the decision to screen individual patients is a matter of clinical judgment. Patients at increased risk for cardiovascular disease may benefit most from screening for type 2 diabetes, since management of cardiovascular risk factors leads to reductions in major cardiovascular events. Clinicians should assist patients in making that choice. In addition, clinicians should be alert to symptoms suggestive of diabetes (i.e., polydipsia and polyuria) and te with these symptoms.
- Screening for diabetes in patients with hypertension or hyperlipidemia should be part of an integrated approach to reduce cardiovascular risk. Lower targets for blood pressure (i.e., diastolic blood pressure <80 mm Hg) are beneficial for patients with diabetes and high blood pressure. The report of the Adult Treatment Panel III of the National Cholesterol Education Program recommends lower targets for low-density lipoprotein cholesterol for patients with diabetes. Attention to other risk factors such as physical inactivity, diet, and overweight is also important, both to decrease risk for heart disease and to improve glucose control.
- Three tests have been used to screen for diabetes: fasting plasma glucose (FPG), 2-hour post-load plasma glucose (2-hour PG), and hemoglobin A1c (HbA1c). The American Diabetes Association (ADA) has recommended the FPG test (>126 mg/dl) for screening because it is easier and faster to perform, more convenient and acceptable to patients, and less expensive than other screening tests. The FPG test is more reproducible than the 2-hour PG test, has less intraindividual variation, and has similar predictive value for development of microvascular complications of diabetes. Compared with the FPG test, the 2-hour PG test may lead to more individuals being diagnosed as diabetic. HbA1c is more closely related to FPG than to 2-hour PG, but at the usual cut-points it is less sensitive in detecting lower levels of hyperglycemia. The random capillary blood glucose (CBG) test has been shown to have reasonable sensitivity (75% at a cut-point of >120 mg/dl) in detecting persons who have either an FPG level >126 mg/dl or a 2-hour PG level >200 mg/dl, if results are interpreted according to age and time since last meal; however, the random blood glucose test is less well standardized for screening for diabetes.
- The ADA recommends confirmation of a diagnosis of diabetes with a repeated FPG test on a separate day, especially for patients with borderline FPG results and patients with normal FPG levels for whom suspicion of diabetes is high. The optimal screening interval is not known. The ADA, on the basis of expert opinion, recommends an interval of every 3 years but shorter intervals in high-risk persons.
- Regardless of whether the clinician and patient decide to screen for diabetes, patients should be encouraged to exercise, eat a healthy diet, and maintain a healthy weight, choices that may prevent or forestall the development of type 2 diabetes. More aggressive interventions to establish and maintain these behaviors should be considered for patients at increased risk for developing diabetes, such as those who are overweight, have a family history of diabetes, or have a racial or ethnic background associated with an increased risk (e.g., American Indians). Intensive programs of lifestyle modification (diet, exercise, and behavior) should also be considered for patients who have impaired fasting glucose or impaired glucose tolerance, since several large trials have demonstrated that these programs can significantly reduce the incidence of diabetes in these patients. Evidence and recommendations regarding counseling about diet, physical activity, and obesity are provided in the USPSTF evidence summaries "Counseling to Promote a Healthy Diet," "Counseling to Promote Physical Activity," and "Screening and Treatment for Obesity in Adults," available on the Agency for Healthcare Research and Quality website at http://www.preventiveservices.ahrq.gov.

8. MUSCULOSKELETAL CONDITIONS

A. PRIMARY CARE INTERVENTIONS TO PREVENT LOW BACK PAIN IN ADULTS

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) concludes that the evidence is insufficient to recommend for or against the routine use of interventions to prevent low back pain in adults in primary care settings. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Although exercise has not been shown to prevent low back pain, regular physical activity has other proven health benefits, including prevention of cardiovascular disease, hypertension, type 2 diabetes, obesity, and osteoporosis.
- Neither lumbar supports nor back belts appear to be effective in reducing the incidence of low back pain.
- Worksite interventions, including educational interventions, have some short-term benefit in reducing the incidence of low back pain. However, their applicability to the primary care setting is unknown.
- Back schools may prevent further back injury for individuals with recurrent or chronic low back pain, but their long-term effectiveness has not been well studied.

B. SCREENING FOR OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) recommends that women aged 65 and older be screened routinely for osteoporosis. The USPSTF recommends that routine screening begin at age 60 for women at increased risk for osteoporotic fractures (see Clinical Considerations for discussion of women at increased risk). *Rating: B Recommendation.*

The USPSTF makes no recommendation for or against routine osteoporosis screening in postmenopausal women who are younger than 60 or in women aged 60-64 who are not at increased risk for osteoporotic fractures. *Rating: C Recommendation.*

CLINICAL CONSIDERATIONS

- Modeling analysis suggests that the absolute benefits of screening for osteoporosis among women aged 60-64 who are at increased risk for osteoporosis and fracture are comparable to those of routine screening in older women. The exact risk factors that should trigger screening in this age group are difficult to specify based on evidence. Lower body weight (weight $<$ 70 kg) is the single best predictor of low bone mineral density.[1,2] Low weight and no current use of estrogen therapy are incorporated with age into the 3-item Osteoporosis Risk Assessment Instrument (ORAI).[1,2] There is less evidence to support the use of other individual risk factors (for example, smoking, weight loss, family history, decreased physical activity, alcohol or caffeine use, or low calcium and vitamin D intake) as a basis for identifying high-risk women younger than 65. At any given age, African-American women on average have higher bone mineral density (BMD) than white women and are thus less likely to benefit from screening.
- Among different bone measurement tests performed at various anatomical sites, bone density measured at the femoral neck by dual-energy x-ray absorptiometry (DXA) is the best predictor of hip fracture and is comparable to forearm measurements for predicting fractures at other sites. Other technologies for measuring peripheral sites include quantitative ultrasonography (QUS), radiographic absorptiometry, single energy x-ray absorptiometry, peripheral dual-energy x-ray absorptiometry, and peripheral quantitative computed tomography. Recent data suggest that peripheral bone density testing in the primary care setting can also identify postmenopausal women who have a higher risk for fracture over the short term (1 year). Further research is needed to determine the accuracy of peripheral bone density testing in comparison with dual-energy x-ray absorptiometry (DXA). The likelihood of being diagnosed with osteoporosis varies greatly depending on the site and type of bone measurement test, the number of sites tested, the brand of densitometer used, and the relevance of the reference range.
- Estimates of the benefits of detecting and treating osteoporosis are based largely on studies of bisphosphonates. Some women, however, may prefer other treatment options (for example, hormone replacement therapy, selective estrogen receptor modulators, or calcitonin) based on personal preferences or risk factors. Clinicians should review with patients the relative benefits and harms of available treatment options, and uncertainties about their efficacy and safety, to facilitate an informed choice.
- No studies have evaluated the optimal intervals for repeated screening. Because of limitations in the precision of testing, a minimum of 2 years may be needed to reliably measure a change in bone mineral density; however, longer intervals may be adequate for repeated screening to identify new cases of osteoporosis. Yield of repeated screening will be higher in older women, those with lower BMD at baseline, and those with other risk factors for fracture.
- There are no data to determine the appropriate age to stop screening and few data on osteoporosis treatment in women older than 85. Patients who receive a diagnosis of osteoporosis fall outside the context of screening but may require additional testing for diagnostic purposes or to monitor response to treatment.

9. VISION DISORDERS

A. SCREENING FOR GLAUCOMA

Summary of Recommendation

The U.S. Preventive Services Task Force (USPSTF) found insufficient evidence to recommend for or against screening adults for glaucoma. *Rating: I Recommendation.*

CLINICAL CONSIDERATIONS

- Primary open angle glaucoma (POAG) is a chronic condition characterized by a loss of retinal ganglion cell axons. It is manifested initially by peripheral visual field loss; in an uncertain number of cases, it progresses to impairment in important vision-related function and even to irreversible blindness.
- The diagnosis of POAG is not made on the basis of a single test but on the finding of characteristic degenerative changes in the optic disc and defects in visual fields. Although increased intraocular pressure (IOP) has previously been considered an important part in the definition of this condition, it is now known that many people with POAG do not have increased IOP; hence, there is little value of using tonometry to screen for POAG.
- Increased IOP, family history, older age, and being of African American descent place an individual at increased risk for glaucoma. Older African Americans have a higher prevalence of glaucoma and perhaps a more rapid disease progression, and if it is shown that screening for glaucoma reduces the development of visual impairment, African Americans would likely have greater absolute benefit than whites. People with a limited life expectancy would likely have little to gain from glaucoma screening.
- The natural history of glaucoma is heterogeneous and not well defined. There is a subgroup of people with POAG in whom there is either no disease progression, or the progression is so slow that the condi-

tion would never have an important effect on their vision. The size of this subgroup is uncertain and may depend on the ethnicity and age of the population. Others experience more rapidly progressing disease, leading to reduced vision-related function within 10 years. Whether an individual's glaucoma will progress cannot be predicted with precision, but those with higher levels of IOP and worse visual fields at baseline, and those who are older, tend to be at greater risk for the more rapid progression of glaucoma. Whether the rate of progression of visual field defects remains uniform throughout the course of glaucoma is unknown.

- Measurement of visual fields can be difficult. The reliability of a single visual field measurement may be low; several consistent visual field measurements are needed to establish the presence of defects. Dilated ophthalmoscopy or slit lamp exam are used by specialists to examine changes in the optic disc; however, even experts vary in their ability to detect glaucomatous optic disc progression. Additionally, there is no agreed-upon single standard to define and measure progression of visual field defects. The primary treatments for POAG reduce IOP; these include medications, laser therapy, or surgery. These treatments effectively reduce the development and progression of small, visual field defects. The magnitude of their effectiveness, however, in reducing impairment in vision-related function is uncertain. Harms caused by these interventions include formation of cataracts, harms resulting from cataract surgery, and harms of topical medication.

Appendix Ia

Dietary Supplements: What Every Primary Care Provider Should Know

Primary care providers must be knowledgeable regarding the safety, efficacy, and drug interactions associated with common dietary supplements because of the following:

- An estimated 38% of adults ages 18 years and older reported the use of at least one form of complementary and alternative medicine (CAM) according to the National Health Interview Survey in 2007.
- Almost 17.8% of adults specifically reported the use of dietary supplements, with fish oil, glucosamine, echinacea, flaxseed, and ginseng most frequently used.
- Although the use of dietary supplements has plateaued as a result of consumer concerns about effectiveness and potential adverse effects, usage remains common and potentially dangerous.

COMMON TERMINOLOGY

- A *dietary supplement* is defined as an oral product containing vitamins, minerals, herbs, or other botanicals; amino acids; dietary substances used to supplement the diet by increasing the total dietary intake; or a concentrate, metabolite, constituent, extract, or combination.
- *CAM* refers to the broad domain of healing practices that include diverse health systems, modalities, and practices and their accompanying theories and beliefs (see glossary of terms in Appendix Id).
- *Complementary therapies* are those that are used *in addition to* conventional therapies, whereas *alternative therapies* are those that are used *instead of* conventional therapies. Most consumers in the United States use dietary supplements as a complementary therapy.
- *Standardization* refers to the practice of producing dietary supplements with a specific amount of a given compound that may or may not include the actual active ingredient. For example, feverfew has been standardized to its parthenolide content.

LEGISLATION

The U.S. Food and Drug Administration (FDA) is frequently criticized for not closely regulating dietary supplements and monitoring their safety. However, although the agency regulates prescription drugs and over-the-counter (OTC) products, the FDA has limited regulatory authority over dietary supplements. This is because the Dietary Supplement and Health Education Act (DSHEA) of 1994 and its resulting regulations limit the FDA's authority. As a result of DSHEA, the FDA is able to act only when a dietary supplement has been documented to contain a prescription drug, as was the case with glyburide in a natural treatment for diabetes and diazepam in an osteoarthritis preparation. In addition, the FDA can act when safety issues related to a product have been clearly documented, although these cases are frequently challenged in the courts.

HEALTH CLAIMS

Dietary supplements generally are marketed under three types of health claims. The first category is the "nutrient content" claim, in which the product is identified as an excellent source of, typically, a mineral such as calcium, based on recommended daily values. The second type is the "significant scientific agreement" claim; these claims are used when some evidence of the product's efficacy exists (e.g., fish oil supplements). The third and most common type of health claim is called a "structure/function" claim; these claims state that the product has some effect on health—for example, "helps to maintain a healthy heart." However, dietary supplements are not permitted to carry claims stating that they are effective in preventing, treating, or curing diseases.

INFORMATION RESOURCES

Appendix 1b provides a brief overview of common dietary supplements. Until recently, few evidence-based resources on dietary supplements were available. Clinical studies and systematic reviews on dietary supplements are now widely available through PubMed, EMBASE, and the Cochrane Database of Systematic Reviews. Although more information is available, references on specific products vary in their interpretation of the available evidence and may exhibit an unintentional bias, either pro or con, regarding the safety and efficacy of dietary supplements.

"Gold standard" evidence-based databases on dietary supplements (subscription required) include the following:

- Natural Medicines Comprehensive Database (http://www.naturaldatabase.com): This database includes listings for many dietary supplements and is organized in a clinician-friendly manner. Monographs include the different common and scientific names; uses and likely effectiveness for different uses; chemical constituents; interactions with drugs, diseases, foods, and laboratory tests; adverse effects; and cautions. The information is extensively referenced and is updated on a daily basis. The primary limitation is that the evaluation of data on clinical effectiveness could be more rigorous.
- Natural Standard (http://www.naturalstandard.com): This database includes listings for dietary supplements and other forms of complementary and alternative medicine. The evidence supporting the assessments in this database is critically evaluated and rigorous in nature. The primary limitation is that many fewer dietary supplements are included in this database.

Evidence-based free websites on dietary supplements include the following:

- National Center for Complementary and Alternative Medicine (NCCAM) (http://nccam.nih.gov)
- Office of Dietary Supplements International Bibliographic Information on Dietary Supplements (http://dietary-supplements.info.nih.gov/Health_Information/IBIDS.aspx)
- Memorial Sloan-Kettering Cancer Center (http://www.mskcc.org/mskcc/html/11570.cfm)

DRUG INTERACTIONS

Clinically significant interactions have been documented between dietary supplements and prescription or OTC drugs. The challenge for primary care providers is to identify real, clinically relevant interactions versus potential or theoretical interactions. Data on interactions with dietary supplements are usually based on isolated case reports or on studies enrolling healthy volunteers. As with drug-drug interactions, the likelihood of an interaction and its severity are influenced especially by concomitant medical conditions, such as heart failure and presence or absence of impaired kidney and liver function.

Appendix Ic lists interactions between selected natural products and prescription and nonprescription drugs. The following two broad interactions are particularly important in primary care practice:

- St. John's wort, commonly used for depression, is a potent inducer of cytochrome P450 3A4 isoenzymes and has been documented to increase the clearance of many drugs that are metabolized through this (and other) pathways. (For a list of common drugs cleared in this manner, readers should consult http://medicine.iupui.edu/flockhart/clinlist.htm.) In addition, St. John's wort may also induce p-glycoprotein transporter systems that are important for digoxin and some chemotherapeutic agents. St. John's wort has also been associated with the development of serotonin syndrome when used with drugs that have significant serotonergic activity.
- Dietary supplements such as garlic, ginkgo, and feverfew, as well as many others, have been purported to either have antiplatelet activity or have effects on the clotting cascade. This may be important for adults also taking aspirin (and other platelet-active agents) or warfarin.

COUNSELING POINTS

The single most important counseling point related to dietary supplements is always to ask patients about their use of these products and to do so in an open, nonjudgmental manner. The approach should emphasize that many consumers have been interested in vitamins, minerals, herbs, teas, and so on, to maintain their health or to treat illness. If the clinician is unaware of the safety, efficacy, and interactions of a specific product, several websites are available to quickly scan for information. Also, access to drug information centers at colleges of pharmacy is almost always available, and some hospitals now offer programs in integrative medicine.

Patients should be asked about their goals in using the product, as well as how long they have taken it and in what dosage. Allergies to plants should be documented because cross-allergies are common. Clinicians should appreciate that an individual who uses dietary supplements may be interested in making lifestyle changes and potentially decreasing their use of prescription drugs. In addition, if an individual is also consulting an alternative medicine practitioner, clinicians should recognize that some alternative health systems discourage the use of established therapies such as vaccines.

Although problems with safety and efficacy have been identified, many dietary supplements are benign except for their cost. Some patients are at higher risk for adverse outcomes from the use of dietary supplements (e.g., those with chronic kidney and liver disease). Patients should be counseled specifically to avoid purchasing dietary supplements over the Internet.

RESEARCH ISSUES

Many clinical and observational studies of dietary supplements have been published. In the past, clinicians frequently stated that published studies of dietary supplements either did not exist or only a few were available. The reason for this finding was that until recently the National Library of Medicine did not abstract from the peer-reviewed alternative medicine literature. Fortunately, much more research is now readily available. As with all research, the more rigorous the study methodology, the less likely the dietary supplement is to demonstrate clinical benefit.

In evaluating published studies of dietary supplements, the following should be considered:

- Has the correct plant and part of the plant (root, stem, leaf) been used? This critical information may not be known to many clinicians. Consulting a resource such as the National Medicines Comprehensive Database can usually provide the needed information to judge this component of the study.
- Has the content of active ingredients been verified throughout the study? In a recent review of 81 major randomized controlled trials of herbal products, only 12 (15%) reported performing tests to quantify actual contents, and 3 (4%) provided adequate data to compare actual with expected content values of at least one chemical constituent.
- Is the severity of the disease appropriate for study? Negative studies with dietary supplements sometimes inappropriately enroll participants who have moderate-to-severe disease (e.g., those with depression or benign prostatic hyperplasia) when only mild disease would be appropriate.
- Is the duration of the study appropriate? Early studies comparing glucosamine and nonsteroidal anti-inflammatory agents (NSAIA) demonstrated greater efficacy with the NSAIA because of an inadequate study duration for glucosamine to show any benefit.
- Is a placebo group included? Recent studies with dietary supplements for menopausal symptoms and osteoarthritis have demonstrated placebo responses over 40% to 50%.
- Was the blinding maintained throughout the study? Some dietary supplements, such as saw palmetto, have distinctive odors and tastes that are not easily masked.
- Is the preparation commercially available? Most importantly, when a study with dietary supplements does show benefit, it frequently is difficult to use the product in practice because the specific formulation studied is not commercially available.

AUTHOR: **ANNE L. HUME, PHARM.D.**

Appendix Ib

Overview of Selected Natural Products

This table includes a few of the common uses and side effects of selected natural products. The evidence supporting the uses and side effects of these products varies considerably and may be based on anecdotal information or theoretical concerns with the natural products.

Natural Products	Common Use(s)	Adverse Effects/Potential Concerns
African plum (Pygeum)	Benign prostatic hyperplasia	Nausea and abdominal pain have been reported, but pygeum is generally well tolerated. Pygeum does not decrease prostate size or influence PSA concentrations.
Andrographis	Prevention and treatment of viral respiratory infections	Headache, fatigue, rash, diarrhea, and vomiting. Products are standardized to 4%-6% andrographolide; this botanical is commonly used in combination products.
Black cohosh	Menopausal symptoms (hot flashes), induction of labor in pregnant women, premenstrual syndrome	Dyspepsia, rash, weight gain, headache, and cramping have been reported. Concern exists that black cohosh causes liver toxicity. The potential development of mild estrogen-like adverse effects, especially endometrial hyperplasia, is of concern.
Butterbur	Prevention of migraine headaches; allergic rhinitis; urinary tract spasms; pain	Diarrhea, stomach upset, fatigue, belching, headache, and drowsiness may occur. Due to concern about hepatotoxicity, butterbur products should be free of pyrrolizidine alkaloids. Products should be standardized to 15% petasin and isopetasin.
Chamomile (German)	Motion sickness, anxiety, insomnia; gastrointestinal spasms; mucositis	Allergic reactions occur on rare occasion. Patients with a ragweed allergy should use chamomile with caution.
Chasteberry	Premenstrual dysphoric disorder, premenstrual syndrome, menopausal symptoms, female infertility, mastalgia	Gastrointestinal upset, headache, rash, acne, weight gain, and menstrual bleeding have been reported.
Chitosan	Weight loss, Crohn's disease, hypercholesterolemia, anemia	Gastrointestinal upset, nausea, flatulence, and constipation have been reported. Patients with a shellfish allergy should avoid the use of chitosan.
Chondroitin sulfate	Osteoarthritis, osteoporosis, hyperlipidemia	Gastrointestinal upset, nausea, diarrhea, constipation, and alopecia. Concern exists that chondroitin may have anticoagulant activity due to its structural similarity to part of heparin.
Cinnamon	Type 2 diabetes mellitus, flatulence, gastrointestinal spasms, anorexia, menopausal symptoms, impotence	Cassia cinnamon is one of three types of cinnamon in commercial food products; this is the only type that may have minor effects to improve blood glucose concentrations.
Coenzyme Q10	Congestive heart failure, angina, dilated cardiomyopathy, statin-induced myopathy, Parkinson's disease, chronic fatigue syndrome, HIV/AIDS	Nausea, vomiting, diarrhea, anorexia, heartburn, and rash have been reported. Coenzyme Q10 is structurally similar to vitamin K; concern exists about potential interaction with warfarin.
Cranberry	Prevention and treatment of urinary tract infections; type 2 diabetes mellitus; chronic fatigue syndrome; pleurisy	Gastrointestinal upset and diarrhea have been reported with large doses of cranberry. Uric acid kidney stone formation is also possible with large doses of cranberry over prolonged periods of time.
Dehydroepiandrosterone (DHEA)	Slow or reverse aging, weight loss, metabolic syndrome, erectile dysfunction, immune stimulant, osteoporosis, systemic lupus erythematosus, multiple sclerosis, depression, schizophrenia	Acne and other androgenic effects commonly occur in women. Alopecia, insulin resistance, hepatic dysfunction, and hypertension have been reported. Ingested wild yam and soy cannot be converted into DHEA by humans.
Devil's claw	Osteoarthritis, atherosclerosis, gout, myalgias, fever, migraines	Diarrhea, nausea, and vomiting, as well as allergic reactions, have been reported.

AIDS, Acquired immune deficiency syndrome; *HIV,* human immunodeficiency virus.

Continued on following page

Overview of Selected Natural Products

Natural Products	Common Use(s)	Adverse Effects/Potential Concerns
Echinacea	Prevention and treatment of viral respiratory infections; urinary tract infections; chronic fatigue syndrome; attention deficit hyperactivity disorder	Nausea, vomiting, diarrhea, heartburn, headaches, dizziness, arthralgias, and allergic reactions have been reported with echinacea. Patients with a ragweed allergy should use echinacea with caution because the risk of allergic reactions may be increased.
Eleuthero (Siberian ginseng)	Maintenance of a normal blood pressure; atherosclerosis; Alzheimer's disease; chronic fatigue syndrome; diabetes; herpes simplex infections	Drowsiness, anxiety, and irritability have been reported.
Evening primrose oil (EPO)	Premenstrual syndrome, mastalgia, osteoporosis, asthma, menopausal symptoms, eczema, chronic fatigue syndrome	EPO is well tolerated.
Fenugreek	Type 2 diabetes mellitus, anorexia, atherosclerosis; also used as galactogogue	Gastrointestinal upset, flatulence, and hypoglycemia are possible side effects. Patients with a peanut allergy (and an allergy to related plants) should use fenugreek with caution. Nursing mothers who use fenugreek may notice a "maple syrup" smell in their sweat and in the urine of their infants. This may be mistaken to be "Maple Syrup Urine Disease" in the infant.
Feverfew	Prevention of migraines; fever; menstrual-related problems; arthritis; infertility; asthma	Gastrointestinal side effects are the most common with feverfew. A "post-feverfew syndrome" has been reported in individuals who have taken feverfew for prolonged periods of time and then have abruptly stopped the herbal.
Fish oil	Hypertriglyceridemia, coronary heart disease, hypertension, asthma, depression, rheumatoid arthritis, osteoporosis, psoriasis	Heartburn, nausea, rash, and a "fishy" aftertaste can occur. Contamination with pesticides (as well as with mercury and other heavy metals) is a potential concern, although this is unlikely.
Garlic	Hyperlipidemia, hypertension, peripheral arterial disease, type 2 diabetes mellitus	Nausea, vomiting, heartburn, and body odor are most common. "Deodorized" garlic products may lack the active ingredient, allicin.
Ginger	Nausea and vomiting secondary to pregnancy, chemotherapy, motion sickness, surgery	Heartburn, belching, and dermatitis have been reported. In overdoses, ginger has been associated with central nervous system depression and arrhythmias. Efficacy for hyperemesis gravidarum is unknown, and use is not recommended.
Ginkgo	Alzheimer's disease, vascular dementias, tinnitus, acute mountain sickness, intermittent claudication	Gastrointestinal side effects, headaches, dizziness, and allergic skin reactions. Seizures have been reported in several case reports. Products should contain 24% ginkgo flavone glycosides and 6% terpenoids.
Ginseng (Panax)	Increased resistance to stress and improved well-being; increased physical stamina; depression; diabetes; erectile dysfunction	Insomnia has been reported with ginseng. Vaginal bleeding, mastalgia, and amenorrhea have also been reported.
Glucosamine sulfate	Osteoarthritis	Nausea, heartburn, skin reactions, and headache have been reported. Increased glucose concentrations have been a concern but have not been well documented. Patients with a shellfish allergy should use glucosamine with caution.
Green tea	Improve cognitive performance; prevention of breast, prostate, and colon cancer; hyperlipidemia; Parkinson's disease; obesity; diabetes; cardiovascular disease	Nausea, vomiting, dyspepsia, dizziness, insomnia, and nervousness have been reported. Side effects may be a result of the large amount of caffeine in green tea products. Hepatotoxicity has been a potential concern with green tea.
Hawthorn	Mild heart failure, angina, arrhythmias, hypertension	Mild gastrointestinal effects, dizziness, rash, palpitations, and nervousness have been reported.
Hoodia	Obesity	Side effects have not been reported. Many products lack the actual ingredient.
Horse chestnut	Chronic venous insufficiency, including varicose veins; benign prostate hyperplasia; diarrhea	Mild nausea, vomiting, dizziness, headache, and itching. Products are standardized to 16%-20% aescin.
Huperzine	Alzheimer's disease, increased alertness and energy, myasthenia gravis, memory enhancement	Nausea, vomiting, diarrhea, sweating, and blurred vision as a result of the cholinergic effects of huperzine have been reported.
Kava	Anxiety, insomnia, restlessness, seizure disorders, depression, chronic fatigue syndrome	Gastrointestinal upset, headache, dizziness, "kava" dermopathy, and allergic skin reactions. Hepatotoxicity is the primary concern with kava; some countries have banned the use of kava.
Melatonin	Jet lag, insomnia, migraine, chronic fatigue syndrome, breast cancer, osteoporosis; also used for insomnia in children with ADHD	Daytime drowsiness, headache, and dizziness have been reported. Vaginal bleeding has occurred in perimenopausal women. Melatonin from animal sources should be avoided.
Melissa	Cold sores (topically), anxiety, insomnia, Alzheimer's disease, hypertension, dyspepsia	Nausea, vomiting, dizziness, and wheezing have occurred with oral melissa.
Methylsulfonylmethane (MSM)	Chronic pain, arthritis, diabetes, osteoporosis, allergies, obesity, premenstrual syndrome	Nausea, bloating, diarrhea, fatigue, and insomnia have been associated with MSM. This substance is used frequently in combination with glucosamine and chondroitin.
Milk thistle	Protective agent against liver damage due to alcohol, acetaminophen, and carbon tetrachloride; hepatitis C	Nausea, abdominal fullness, diarrhea, and allergic reactions. Patients with a ragweed allergy should use milk thistle with caution.
Peppermint	Irritable bowel syndrome, sinusitis, morning sickness, dysmenorrhea	Heartburn has been reported, as well as laryngeal and bronchial spasm in infants and children.

Natural Products	Common Use(s)	Adverse Effects/Potential Concerns
Policosanol	Hyperlipidemia, intermittent claudication, atherosclerosis	Migraines, insomnia, dizziness, skin rash, and bleeding have been reported with policosanol. The product has antiplatelet effects.
Probiotics	Treatment and prevention of diarrhea including antibiotic-associated diarrhea; irritable bowel syndrome; atopic dermatitis; Crohn's disease	Theoretically, probiotic products may increase risk of infections in immunocompromised individuals.
Red clover phytoestrogens	Menopausal symptoms, premenstrual syndrome, asthma	Rash, myalgias, headaches, and vaginal bleeding have been reported. Theoretically, endometrial hyperplasia is an adverse effect from the use of these compounds.
Red yeast rice	Hyperlipidemia, indigestion, diarrhea, circulatory conditions, HIV/AIDS	Gastrointestinal upset and dizziness may occur. Red yeast rice may contain lovastatin-like compounds and potentially cause rhabdomyolysis.
S-adenosylmethionine (SAM-e)	Depression, anxiety, dementia, osteoarthritis, heart disease	Nausea, vomiting, diarrhea, headache, and nervousness have been reported. Concern exists that SAM-e raises homocysteine levels.
St. John's wort	Depression, anxiety, chronic fatigue syndrome, HIV/AIDS	Anxiety, gastrointestinal upset, vaginal bleeding, neuropathy, and rash can occur. Hypomania has been induced by St. John's wort.
Tea tree oil	Topical use for acne, fungal infections, lice, scabies	Local inflammation and contact dermatitis may occur.
Valerian	Insomnia, depression, chronic fatigue syndrome, menstrual cramps	Headaches, gastrointestinal upset, and drowsiness can occur. Hepatotoxicity is a potential concern with valerian.

Appendix Ic

Natural Products and Drug Interactions

This table lists interactions between selected natural products and prescription and nonprescription drugs. Although many of the listed interactions are theoretical in nature and have not been documented to occur in humans, those involving St. John's wort are potentially life threatening in nature, depending on the individual drug. Other interactions are based on small studies of healthy volunteers and use pharmaceutical-quality natural products that may or may not be commercially available.

Natural Products	Drugs	Interactions
Andrographis	Immune suppressants	Andrographis may stimulate immune function, potentially decreasing the effectiveness of drugs such as cyclosporine, tacrolimus, and prednisone.
	Antihypertensive agents	Andrographis may lower blood pressure, potentiating the hypotensive effects of antihypertensive agents.
	Antiplatelet and anticoagulant agents	Andrographis may have antiplatelet activity, potentially increasing the risk of bleeding.
Black cohosh	Hepatotoxic drugs	Concern exists that the risk of hepatotoxicity with black cohosh is increased in the presence of hepatotoxic drugs such as acetaminophen.
	Cisplatin	Animal studies suggest that the efficacy of cisplatin against breast cancer cells may be decreased by black cohosh.
	CYP2D6 substrates	Black cohosh may modestly inhibit CYP2D6 enzyme activity to result in higher drug concentrations.
Butterbur	CYP3A4 inducers (Rifampin, carbamazepine, etc.)	Drugs that induce the activity of CYP3A4 increase the risk of the formation of hepatotoxic metabolites from pyrrolizidine alkaloids from some butterbur products.
Chamomile	CNS depressants (benzodiazepines, opiates, barbiturates, etc.)	Chamomile may have additive CNS depressant effects.
	CYP1A2 substrates	Chamomile may inhibit CYP1A2 enzyme activity to result in higher drug concentrations.
	CYP3A4 substrates	Chamomile may inhibit CYP3A4 enzyme activity to result in higher drug concentrations.
	Estrogens	Chamomile may compete for estrogen receptors.
	Tamoxifen	Chamomile may interfere with the effects of tamoxifen because of its estrogenic effects.
Chaste tree berry	Antipsychotic agents	Chaste tree berry may antagonize the effects of antipsychotic agents through its dopaminergic activity.
	Metoclopramide	Chaste tree berry may antagonize the effects of metoclopramide through its dopaminergic activity.
	Dopamine agonists	Chaste tree berry may possess additive effects to drugs such as levodopa and ropinirole through its dopaminergic activity.
	Oral contraceptives/estrogens	Chaste tree berry may possess additive hormonal effects.
Chondroitin	Warfarin	High-dose chondroitin has structural similarity to a heparinoid and may possess weak anticoagulant effects.
Cinnamon	Hypoglycemic agents	Cinnamon may possess additive effects on blood glucose to those of hypoglycemic agents.
Coenzyme Q10	Antihypertensive agents	Coenzyme Q10 may possess additive effects on blood pressure to those of antihypertensive agents.
	Warfarin	Coenzyme Q10 may lessen the anticoagulant effects of warfarin because of its structural similarity to vitamin K.
	Chemotherapy	The antioxidant effects of coenzyme Q10 may blunt the efficacy of certain chemotherapeutic agents that depend on the formation of free radicals.
Cranberry	CYP2C9 substrates (warfarin)	Cranberry may inhibit CYP2C9 enzyme activity to result in higher drug concentrations; evidence with warfarin is contradictory.
Dehydroepiandrosterone (DHEA)	Tamoxifen and aromatase inhibitors such as anastrozole and exemestane	DHEA may interfere with the antiestrogenic effects of these drugs.
	CYP3A4 substrates	DHEA may slightly inhibit CYP3A4 enzyme activity to result in higher drug concentrations.

AChE, Acetylcholinesterase; *CCB,* calcium channel blockers; *CNS,* central nervous system; *MAOI,* monoamine oxidase inhibitor; *PPI,* proton pump inhibitors; *SSRI,* selective serotonin reuptake inhibitors.

Continued on following page

Natural Products	Drugs	Interactions
Devil's claw	Antihypertensive agents	Devil's claw may possess additive effects on blood pressure to those of antihypertensive agents.
	Hypoglycemic agents	Devil's claw may possess additive effects on blood glucose to those of hypoglycemic agents.
	H_2 antagonists and PPI	Devil's claw may raise gastric pH and blunt the efficacy of H_2 antagonists and PPI.
	CYP3A4 substrates	Devil's claw may inhibit CYP3A4 enzyme activity to result in higher drug concentrations.
	CYP2C9 substrates	Devil's claw may inhibit CYP2C9 enzyme activity to result in higher drug concentrations.
	CYP2C19 substrates	Devil's claw may inhibit CYP2C19 enzyme activity to result in higher drug concentrations.
	Warfarin	Devil's claw may inhibit CYP2C9 enzyme activity to result in higher concentrations of warfarin; purpura has been reported.
Echinacea	Immune suppressants	Echinacea may stimulate immune function, potentially decreasing the effectiveness of drugs such as cyclosporine, tacrolimus, and prednisone.
	CYP3A4 substrates	Echinacea may modestly induce hepatic CYP3A4 enzyme activity to result in lower drug concentrations.
	CYP1A2 substrates	Echinacea may inhibit CYP1A2 enzyme activity to result in higher drug concentrations.
Eleuthero (Siberian ginseng)	CNS depressants (benzodiazepines, opiates, barbiturates, etc.)	Eleuthero may have additive CNS depressant effects.
	Antiplatelet and anticoagulant agents	Eleuthero may have antiplatelet activity, potentially increasing the risk of bleeding.
	CYP3A4 substrates	Eleuthero may inhibit CYP3A4 enzyme activity to result in higher drug concentrations.
	CYP1A2 substrates	Eleuthero may modestly inhibit CYP1A2 enzyme activity to result in higher drug concentrations.
	CYP2C9 substrates	Eleuthero may modestly inhibit CYP2C9 enzyme activity to result in higher drug concentrations.
	CYP2D6 substrates	Eleuthero may inhibit CYP2D6 enzyme activity to result in higher drug concentrations.
	Digoxin	Concentration of digoxin has been reported to increase but without evidence of toxicity.
Evening primrose oil (EPO)	Antiplatelet and anticoagulant agents	EPO may have anticoagulant activity, potentially increasing the risk of bleeding.
Fenugreek	Antiplatelet and anticoagulant agents	Fenugreek may have antiplatelet activity, potentially increasing the risk of bleeding.
	Hypoglycemic agents	Fenugreek may potentially lower blood glucose concentrations and have additive effects with hypoglycemic agents.
Feverfew	Antiplatelet and anticoagulant agents	Feverfew may have antiplatelet activity, potentially increasing the risk of bleeding.
	CYP3A4 substrates	Feverfew may inhibit CYP3A4 enzyme activity to result in higher drug concentrations.
	CYP1A2 substrates	Feverfew may inhibit CYP1A2 enzyme activity to result in higher drug concentrations.
	CYP2C9 substrates	Feverfew may inhibit CYP2C9 enzyme activity to result in higher drug concentrations.
	CYP2C19 substrates	Feverfew may inhibit CYP2C19 enzyme activity to result in higher drug concentrations.
Fish oils (omega-3 fatty acids)	Antiplatelet and anticoagulant agents	Fish oils may have antiplatelet activity, potentially increasing the risk of bleeding, although this has not been documented in humans.
	Antihypertensive agents	Fish oils may possess additive effects on blood pressure to those of antihypertensive agents.
	Oral contraceptives	Oral contraceptives may potentially interfere with the triglyceride-lowering effects of fish oil.
Garlic	Antiplatelet and anticoagulant agents	Garlic may have antiplatelet activity, potentially increasing the risk of bleeding.
	CYP3A4 substrates	Garlic may potentially induce CYP3A4 enzyme activity to result in lower drug concentrations; evidence is contradictory.
	CYP2E1 substrates	Garlic may modestly inhibit CYP2E1 enzyme activity to result in higher drug concentrations.
Ginger	Antiplatelet and anticoagulant agents	Ginger may have antiplatelet activity, potentially increasing the risk of bleeding.
	Hypoglycemic agents	Ginger may potentially lower blood glucose concentrations and have additive effects with hypoglycemic agents.
Ginkgo	Antiplatelet and anticoagulant agents	Ginkgo may have antiplatelet activity, potentially increasing the risk of bleeding.
	CYP2C19 substrates	Ginkgo may induce CYP2C19 enzyme activity to result in lower drug concentrations.
	CYP1A2 substrates	Ginkgo may modestly inhibit CYP1A2 enzyme activity to result in higher drug levels.
	CYP2C9 substrates	Ginkgo may modestly inhibit CYP2C9 enzyme activity to result in higher drug concentrations.
	CYP2D6 substrates	Ginkgo may inhibit CYP2D6 enzyme activity to result in higher drug concentrations.
Ginseng (Panax)	Antiplatelet and anticoagulant agents	Panax ginseng may have antiplatelet properties; American ginseng may decrease the effectiveness (international normalized ration [INR]) of warfarin.
	CYP2D6 substrates	Panax ginseng may modestly inhibit CYP2D6 enzyme activity to result in higher drug concentrations.
	Immune suppressants	Panax ginseng may stimulate immune function, potentially decreasing the effectiveness of drugs such as cyclosporine, tacrolimus, and prednisone.
	Hypoglycemic agents	Panax ginseng may potentially lower blood glucose levels and have additive effects with hypoglycemic agents.
Glucosamine	Warfarin	High-dose glucosamine (along with high-dose chondroitin) may have additive effects to those of warfarin because of structural similarity to heparin.

AChE, Acetylcholinesterase; *CCB,* calcium channel blockers; *CNS,* central nervous system; *MAOI,* monoamine oxidase inhibitor; *PPI,* proton pump inhibitors; *SSRI,* selective serotonin reuptake inhibitors.

Natural Products	Drugs	Interactions
Green tea extract	Antiplatelet agents	Green tea possesses compounds that may have antiplatelet activity, potentially increasing the risk of bleeding.
	Amphetamines	Caffeine in green tea may increase the risk of CNS toxicity.
	Cocaine	Caffeine in green tea may increase the risk of CNS toxicity.
	Oral contraceptives	Oral contraceptives may decrease the clearance of caffeine in green tea.
	Warfarin	Small amounts of vitamin K have been reported to be present in green tea, potentially decreasing the effectiveness of warfarin.
	Theophylline	Caffeine potentially decreases theophylline clearance.
	Verapamil	Verapamil decreases caffeine clearance, resulting in increased concentrations.
	Quinolone antibiotics	Some quinolone antibiotics decrease the clearance of caffeine.
	Hepatotoxic drugs	Concern exists that the risk of hepatotoxicity with green tea is increased in the presence of hepatotoxic drugs such as acetaminophen.
Hawthorn	β-blockers	Hawthorn and β-blockers may have additive effects on blood pressure and heart rate.
	CCB, nitrates	Hawthorn and CCB (or nitrates) may have additive effects due to coronary vasodilation.
	Digoxin	Hawthorn may have additive effects to those of digoxin.
	Phosphodiesterase inhibitors	Hawthorn may have additive vasodilatory and hypotensive effects with sildenafil, tadalafil, and vardenafil.
Horse chestnut seed extract (HCSE)	Antiplatelet and anticoagulant agents	HCSE may have antiplatelet activity, potentially increasing the risk of bleeding.
	Hypoglycemic agents	HCSE may potentially lower blood glucose concentrations and have additive effects with hypoglycemic agents.
Huperzine	AChE inhibitors (donepezil, etc.)	Huperzine may have additive effects when combined with AChE inhibitors.
	Anticholinergic drugs	The effectiveness of huperzine and/or the anticholinergic drug may be decreased by their concomitant administration.
	Cholinergic drugs (bethanechol, neostigmine, etc.)	Huperzine may have additive effects when combined with cholinergic drugs.
Kava	CYP3A4 substrates	Kava may inhibit CYP3A4 enzyme activity to result in higher drug concentrations.
	CYP1A2 substrates	Kava may inhibit CYP1A2 enzyme activity to result in higher drug concentrations.
	CYP2C9 substrates, CYP2C19 substrates	Kava may inhibit CYP2C9 and CYP2C19 enzyme activity to result in higher drug concentrations.
	CYP2D6 substrates	Kava may inhibit CYP2D6 enzyme activity to result in higher drug concentrations.
	P-glycoprotein substrates (digoxin; etoposide, paclitaxel, vinblastine, vincristine; itraconazole; diltiazem, verapamil; and many other drugs)	Kava may inhibit P-glycoprotein transporter systems.
	Hepatotoxic drugs	Concern exists that the risk of hepatotoxicity from kava is increased in the presence of hepatotoxic drugs such as acetaminophen.
Melatonin	Antiplatelet and anticoagulant agents	Melatonin may potentiate the effects of antiplatelets and anticoagulants, although the mechanism is unknown.
	CNS depressants	Melatonin may have additive CNS depressant effects.
	Fluvoxamine	Fluvoxamine may increase levels of melatonin.
	Immune suppressants	Melatonin may stimulate immune function, potentially decreasing the effectiveness of drugs such as cyclosporine, tacrolimus, and prednisone.
	Hypoglycemic agents	Melatonin may impair glucose utilization and may decrease the efficacy of hypoglycemic agents.
Milk thistle	Estrogens (and other drugs that undergo glucuronidation)	Silymarin may increase the clearance of estrogens.
	CYP2C9 substrates	Milk thistle may modestly inhibit CYP2C9 enzyme activity to result in higher drug concentrations.
Peppermint oil	H_2 antagonists and proton pump inhibitors	Peppermint oil may raise gastric pH and blunt efficacy of H_2 antagonists and PPI.
	CYP3A4 substrates	Peppermint oil may modestly inhibit CYP3A4 enzyme activity to result in higher drug concentrations.
	CYP1A2 substrates	Peppermint oil may modestly inhibit CYP1A2 enzyme activity to result in higher drug concentrations.
	CYP2C9 substrates, CYP2C19 substrates	Peppermint oil may modestly inhibit CYP2C9 and CYP2C19 enzyme activity to result in higher drug concentrations.
Policosanol	Antiplatelet and anticoagulant agents	Policosanol may have antiplatelet activity, potentially increasing the risk of bleeding.
Probiotics	Antibiotics	Antibiotics may kill the live organisms in different probiotic preparations.
	Immune suppressants	Theoretically, probiotics may cause bacterial or fungal infections in patients who are taking immune suppressants chronically.

Continued on following page

Natural Products	Drugs	Interactions
Red clover phytoestrogens	Antiplatelet and anticoagulant agents	Theoretically, red clover may possess coumarins, which increase the risk of bleeding with antiplatelet and anticoagulants.
	Tamoxifen/aromatase inhibitors	
	CYP3A4 substrates	Red clover may inhibit CYP3A4 enzyme activity to result in higher drug concentrations.
	CYP2C9 substrates, CYP2C19 substrates	Red clover may inhibit CYP2C9 and CYP2C19 enzyme activity to result in higher drug concentrations.
	CYP1A2 substrates	Red clover may inhibit CYP1A2 enzyme activity to result in higher drug concentrations.
Red yeast rice	CYP3A4 inhibitors	Drugs that inhibit CYP3A4 may decrease the metabolism of lovastatin in red yeast rice.
	Statins	Red yeast rice contains lovastatin and increases the risk of myopathy (and hepatotoxicity).
	Fibrates and niacin	Fibrates and niacin may increase concentrations of lovastatin in red yeast rice.
S-adenosylmethionine (SAM-e)	Antidepressants (including MAOIs)	Additive effects are possible, and there is potential for toxicity.
	Serotonergic drugs (triptans, SSRIs, tramadol, meperidine, dextromethorphan, etc.)	SAM-e may increase the risk of development of serotonin syndrome when used concomitantly.
Soy phytoestrogens	Antibiotics	Antibiotics may decrease the efficacy of soy because intestinal bacteria convert isoflavones into more active forms.
	Estrogens	Soy potentially may inhibit the effects of estrogen.
	Tamoxifen/aromatase inhibitors	Soy's estrogenic effects may antagonize the antitumor effects of tamoxifen/aromatase inhibitors.
	MAOIs	Fermented soy products may contain tyramine.
St. John's wort	CYP3A4 substrates	St. John's wort strongly induces CYP3A4 enzyme activity to result in lower drug concentrations.
	CYP1A2 substrates	St. John's wort modestly induces CYP1A2 enzyme activity to result in lower drug levels.
	CYP2C9 substrates	St. John's wort induces CYP2C9 enzyme activity to result in lower drug concentrations.
	P-glycoprotein substrates (digoxin; etoposide, paclitaxel, vinblastine, vincristine; itraconazole; diltiazem, verapamil; and other drugs)	St. John's wort induces P-glycoprotein transporter systems.
	Serotonergic drugs (triptans, SSRIs, tramadol, meperidine, dextromethorphan, etc.)	St. John's wort may increase the risk of development of serotonin syndrome when used concomitantly.
Valerian	CNS depressants (benzodiazepines, opiates, barbiturates, alcohol, etc.)	Valerian may increase the sedative effects of CNS depressants.
	CYP3A4 substrates	Valerian may modestly inhibit the CYP3A4 enzyme activity.

AChE, Acetylcholinesterase; *CCB,* calcium channel blockers; *CNS,* central nervous system; *MAOI,* monoamine oxidase inhibitor; *PPI,* proton pump inhibitors; *SSRI,* selective serotonin reuptake inhibitors.

EXAMPLES OF DRUGS METABOLIZED BY CYP ENZYMES

The following are example drugs that are metabolized through the different cytochrome P450 isoenzymes:

CYP1A2 substrates: theophylline, imipramine, clozapine, naproxen

CYP2C9 substrates: warfarin, tamoxifen, irbesartan, ibuprofen, glipizide

CYP2C19 substrates: omeprazole and other proton pump inhibitors, phenytoin, phenobarbital, cyclophosphamide

CYP2D6 substrates: S-metoprolol, propafenone, paroxetine, risperidone, tramadol

CYP2E1 substrates: acetaminophen, alcohol

CYP3A4 substrates: most statins, indinavir, amlodipine, verapamil, alprazolam, buspirone

(For a complete list of drugs and their respective metabolic pathways through the cytochrome P450 isoenzyme systems go to http://medicine.iupui.edu/flockhart.)

Appendix Id

Definitions of Complementary and Alternative Medicine Terms

Acupuncture Thin needles are inserted superficially on the skin at locations throughout the body. These points are located along "channels" of energy. Heat can be applied by burning (moxibustion), electric current (electroacupuncture), or pressure (acupressure). Healing is proposed by the restoration of a balance of energy flow called *Qi.* Another explanation suggests that, possibly, the stimulation activates endorphin receptors.

Alexander Technique A bodywork technique in which rebalancing of "postural sets" (i.e., physical alignment) is taught by mentally focusing on the way correct alignments should look and feel and through verbal and tactile guidance by the practitioner.

Applied Kinesiology A form of treatment that uses nutrition, physical manipulation, vitamins, diets, and exercise to restore and energize the body. Weak muscles are proposed as a source of dysfunctional health.

Aromatherapy A form of herbal medicine that uses various oils from plants. Route of administration can be through absorption in the skin or inhalation. The aromatic biochemical structures of certain herbs are thought to act in areas of the brain related to past experiences and emotions (e.g., limbic system).

Ayurveda A major health system that originated in India and incorporates the body, mind, and spirit to prevent and treat disease. Includes special types of diets, herbs, and minerals.

Biofeedback A mind-body therapy procedure in which sensors are placed on the body to measure muscle tension, heart rate, and sweat responses or neural activity. Information is provided by visual, auditory, or body-muscle cell activation so as to teach either to increase or decrease physiologic activity, which, when reconstituted, is proposed to improve health problems (e.g., pain, anxiety, or high blood pressure). In some cases, relaxation exercises complement this procedure.

Chelation Therapy Involves the removal—through intravenous infusion of a chelating agent (synthetic amino acid ethylenediamine tetraacetic acid [EDTA])—of heavy metals, including lead, nickel, and cadmium, as a way to treat certain diseases. Ancillary treatments include the use of vitamins, changes in diet, and exercise.

Cognitive Therapy Psychologic therapy in which the major focus is altering and changing irrational beliefs through a type of Socratic dialogue and self-evaluation of certain illogical thoughts. Conditioning and learning are important components of this therapy.

Craniosacral Therapy A form of gentle manual manipulation used for diagnosis and for making corrections in a system made up of cerebrospinal fluid, cranial and dural membranes, cranial bones, and sacrum. This system is proposed to be dynamic, with its own physiologic frequency. Through touch and pressure, tension is proposed to be reduced and cranial rhythms normalized, leading to improvement in health and disease.

Diathermy The use of high-frequency electrical currents as a form of physical therapy and in surgical procedures. The term *diathermy,* derived from the Greek words *dia* and *therma,* literally means "heating through." The three forms of diathermy used by physical therapists are short wave, ultrasound, and microwave.

Eye Movement Desensitization and Reprocessing (EMDR) A technique that proposes to remove painful memories by behavioral techniques. Rhythmic, multisaccadic eye movements are produced by allowing the patient to track and follow a moving object while imagining a stressful memory or event. By using deconditioning, including verbal interaction with the therapist, the painful memory is extinguished and health improved.

Feldenkrais Method A bodywork technique that integrates physics, judo, and yoga. The practitioner directs sequences of movement using verbal or hands-on techniques or teaches a system of self-directed exercise to treat physical impairments through the learning of new movement patterns.

Hatha Yoga The branch of yoga practice that involves physical exercise, breathing practices, and movement. These exercises are designed to have a salutary effect on posture, flexibility, and strength and are intended ultimately to prepare the body to remain still for long periods of meditation.

Hellerwork A bodywork technique that treats and improves proper body alignment through the development of a more complete awareness of the physical body. The goal is to realign fascia for improvement of standing, sitting, and breathing using "body energy," verbal feedback, and changing emotions and attitudes.

Homeopathy A form of treatment in which substances (minerals, plant extracts, chemicals, or disease-producing germs), which in sufficient doses would produce a set of illness symptoms in healthy individuals, are given in microdoses to produce a "cure" of those same symptoms. The *symptom* is not thought to be part of the illness but part of a curative process.

Hyperbaric Oxygen A therapy in which 100% oxygen is given at or above atmospheric pressure. An increase in oxygen in the tissue is proposed to increase blood circulation and improve healing and health and influence the course of disease.

Jin Shin Jyutsu An ancient bodywork technique to harmonize body, mind, and spirit by gentle touch that uses specific "healing points" at the body surface. The points are proposed to overlie flowing energy (Qi). The therapist's fingers are used to "redirect, balance, and provide a more efficient energy flow" to and throughout the body.

Light Therapy Natural light or light of specified wavelengths is used to treat disease. This may include ultraviolet light, colored light, or low-intensity laser light. Generally, the eye is the initial entry point for the light because of its direct connection to the brain.

Magnetic Therapy Magnets are placed directly on the skin, theoretically stimulating living cells and increasing blood flow by ionic currents that are created from polarities on the magnets.

Modified from Spencer JW: *Complementary/alternative medicine: an evidence-based approach*, St Louis, 1999, Mosby.

Mediterranean Diet A diet that is thought to provide optimal distribution of daily caloric intake of different nutrients and includes 50% to 60% carbohydrates, 30% fats, and 10% proteins. The diet is derived from the eating habits of people in the Mediterranean area, who were shown to have reduced rates of cardiovascular disease.

Mind-Body Therapies A group of therapies that emphasize using the mind or brain in conjunction with the body to assist healing. Mind-body therapies can involve varying degrees of levels of consciousness, including *hypnosis,* in which selective attention is used to induce a specific altered state (trance) for memory retrieval, relaxation, or suggestion; *visual imagery,* in which the focus is on a target visual stimulus; *yoga,* which involves integration of posture and controlled breathing, relaxation, and/or meditation; *relaxation,* which includes lighter levels of altered states of consciousness through indirect or direct focus; and *meditation,* in which there is an intentional use of posture, concentration, contemplation, and visualization.

Muscle Energy Technique A manual therapy in osteopathic medicine that includes both passive mobilization and muscle reeducation. Diagnosis of somatic dysfunction is performed by the practitioner, after which the patient is guided to provide corrective muscle contraction.

Music Therapy The use of music in an either active or passive mode. Used mainly to reduce stress, anxiety, and pain.

Naturopathy A major health system that includes practices that emphasize diet, nutrition, homeopathy, acupuncture, herbal medicine, manipulation, and various mind-body therapies. Focal points include self-healing and treatment through changes in lifestyle and emphasis on health prevention.

Ornish Diet A life-choice program based on eating a vegetarian diet containing less than 10% fat. The diet is high in complex carbohydrates and fiber. Meat and fish are generally avoided.

Oslo Diet An eating plan that emphasizes increased intake of fish and reduced total fat intake. Diet is combined with regular endurance exercise.

Pilates An educational and exercise approach using the proper body mechanics, movements, truncal and pelvic stabilization, coordinated breathing, and muscle contractions to promote strengthening. Attention is paid to the entire musculoskeletal system.

Prayer The use of prayer(s) that are offered to "some higher being" or authority to heal and/or arrest disease. May be practiced by the individual patient, by groups, or by other(s) with or without the patient's knowledge (e.g., intercessory).

Pritikin Diet A weight management plan that is based on a vegetarian framework. Meals are low in fat, high in fiber, and high in complex carbohydrates.

Qi Gong A form of Chinese exercise-stimulation therapy that proposes to improve health by redirecting mental focus, breathing, coordination, and relaxation. The goal is to "rebalance" the body's own healing capacities by activating proposed electrical or energetic currents that flow along meridians located throughout the body. These meridians, however, do not follow conventional nerve or muscle pathways. In Chinese medical training and practice this therapy includes "external Qi," which is energy transmitted from one person to another so as to heal.

Raja Yoga Yoga practice that includes all of the other forms of yoga. The practitioner is instructed to follow moral directives, physical exercises, breathing exercises, meditation, devotion, and service to others to facilitate religious awakening.

Reflexology A bodywork technique that uses reflex points on the hands and feet. Pressure is applied at points that correspond to various body parts, to eliminate blockages thought to produce pain or disease.

Reiki Comes from the Japanese word meaning "universal life force energy." The practitioner serves as a conduit for healing energy directed into the body or energy field of the recipient without physical contact with the body.

Rolfing A bodywork technique that involves the myofascia. The body is realigned by using the hands to apply deep pressure and friction that allows more sufficient posture, movement, and the "release" of emotions from the body.

Shiatsu A Japanese bodywork technique involving finger pressure at specific points on the body mainly to balance "energy" in the body. The major focus is on prevention by keeping the body healthy. The therapy uses more than 600 points on the skin that are proposed to be connected to pathways through which energy flows.

T'ai Chi A technique that uses slow, purposeful motor-physical movements of the body to control and achieve a more balanced physiologic and psychologic state.

Therapeutic Touch A body energy field technique in which hands are passed over the body without actually touching to recreate and change proposed "energy imbalances" for restoring innate healing forces. Verbal interaction between patient and therapist helps maximize effects.

Traditional Chinese Medicine An ancient form of medicine that focuses on prevention and secondarily treats disease with an emphasis on maintaining balance through the body by stimulating a constant, smooth-flowing Qi energy. Herbs, acupuncture, massage, diet, and exercise are also used.

Trager Psychophysical Integration A bodywork technique in which the practitioner enters a meditative state and guides the client through gentle, light, rhythmic, nonintrusive movements. "Mentastics" exercises using self-healing movements are taught to the clients.

Relaxation Techniques

Relaxation Techniques

Relaxation Technique	Summary	Further Resources
Breathing exercise	This is the foundation of most relaxation techniques. Have patients place one hand on the chest and the other on the abdomen. Instruct them to take a slow, deep breath, as if they were sucking in all the air in the room. While doing this, the hand on the abdomen should rise higher than the hand on the chest. This promotes diaphragmatic breathing that increases alveolar expansion in the bases of the lungs. Have them hold the breath for a count of 7 and then exhale. Exhalation should take twice as long as inhalation. Repeat this for a total of five breaths, and encourage patients to do this three times a day.	*Conscious Breathing* by Gay Hendricks is one of many good resources on using breathing for relaxation and health.
Meditation		
Transcendental/The relaxation response	To prevent distracting thoughts, the subject repeats a mantra (a word or sound) over and over again while sitting in a comfortable position. If a distracting thought comes to mind, it is accepted and let go, with the mind focusing again on the mantra.	www.mindbody.harvard.edu or *The Relaxation Response* by Herbert Benson; www.tm.org for information on transcendental meditation.
Mindful meditation	This represents the philosophy of living in the present or in the moment. The *body scan* is one technique where the subject uses breathing to obtain a relaxed state while lying or sitting. The mind progressively focuses on different parts of the body, where it feels any and all sensations intentionally but nonjudgmentally before moving on to another part of the body. A patient with back pain may focus on the quality and characteristics of the pain as if to better understand it and bring it under control.	*Full Catastrophe Living* by Jon Kabat-Zinn describes this technique in full and the program for stress reduction at the University of Massachusetts Medical Center.
Centering prayer	This is a form similar to transcendental meditation that has a more religious foundation. The subject repeats a "sacred word" similar to a mantra. As thoughts come to mind, they are accepted and let go, clearing the mind to become more centered on the spirit within, as if the mind's preoccupied thoughts are the layers of an onion that are peeled away, allowing better understanding of the spirit at the core.	www.Centeringprayer.com; look under "method of centering prayer" for a nondenominational discussion.
Progressive muscle relaxation (PMR)	A form of relaxation in which the subject is attuned to the difference in feeling when the muscles are tensed and then relaxed. In a comfortable position, start by tensing the whole body from head to toe. While doing this, notice the feelings of tightness. Take a deep breath in and as you let it out, let the tension release and the muscles relax. This is then followed by progressive tension and relaxation throughout the body. One may start by clenching the fists and then tensing the arms, shoulders, chest, abdomen, hips, legs, and so on, with each step followed by relaxation.	www.uaex.edu/publications/pub/fshei28.htm is a good review of PMR as well as other relaxation exercises. It is sponsored by the University of Arkansas. *You Must Relax* is a book by the founder of this technique, Edmund Jacobson.
Visualization/Self-hypnosis	The subject uses visualization to recruit images that create a relaxed state. For example, if a person is anxious, visualizing images of a place and a time that were peaceful and comforting would help induce relaxation. This is best used in conjunction with a breathing exercise.	There are many audiocassettes that can guide people through a visualization "script" that can result in relaxation. Emmett Miller is one well-known author.
Autogenic training	This induces a physiologic response by using simple phrases. For example, "My legs are heavy and warm" is meant to increase the blood flow to this area, resulting in relaxation. This is done progressively from head to toe with the use of deep breathing and repetition of the phrase. After completing this, focus attention on any body part that may still be tense, and then focus the breath and phrase to that area until the whole body is relaxed.	The British Autogenic Society at www.autogenictherapy.org.uk is a good resource for more information.

From Rakel RE (ed): *Principles of family practice,* ed 6, Philadelphia, 2002, WB Saunders.

Continued on following page

Relaxation Techniques—cont'd

Relaxation Technique	Summary	Further Resources
Exercise/Movement		
Aerobic	While performing an aerobic exercise, focus attention on a phrase, sound, word, or prayer and passively disregard other thoughts that may enter the mind. Some may focus on their breathing, saying to themselves, "In" with inhalation and "Out" with exhalation, or repeating "one-two, one-two" with each step they take with jogging. Doing this will help the mind focus, preventing other thoughts that may cause tension.	*Beyond the Relaxation Response* by Herbert Benson includes discussion of his research on inducing the relaxation response while exercising.
Yoga	This has been practiced for thousands of years in India. In America, it has been divided into three aspects: breathing (pranayama yoga), bodily postures or asanas (hatha yoga), and meditation to maintain balance and health. Regular practice induces relaxation.	For the following therapies, it is best to encourage patients to take a class at a local community center or gym and to pick up an introductory book at a library or bookstore.
T'ai chi	An ancient Chinese martial art that uses slow, graceful movements combined with inner mindfulness and breathing techniques to help bring balance between the mind and body.	See above.
Qi gong	A traditional Chinese practice that uses movement, meditation, and controlled breathing to balance the body's vital energy force, Qi.	See above.

Appendix II

Primary Care Procedures

1. **Anesthesia**
   a. Local anesthesia
   b. Topical anesthesia
   c. Digital block
2. **Biopsy techniques**
   a. Excisional skin biopsy
   b. Punch biopsy
   c. Shave biopsy
3. **Sutures and dressings**
   a. Instrument tie
   b. Inverted subcuticular stitches
   c. Subcuticular running stitches
   d. Mattress stitches
   e. Tissue glue
   f. Topical hemostasis
   g. Unna boot application
4. **Needle aspiration**
   a. Breast cyst aspiration
5. **Dermatology**
   a. Skin tag removal
   b. Wart treatment
   c. Abscess incision and drainage
   d. Basal cell curettage and cautery
   e. Lipoma removal
   f. Ingrown toenail removal
6. **Eye, ears, nose, throat**
   a. Nasopharyngoscopy
   b. Cerumen impaction removal
7. **Hand/Digit**
   a. Ring removal
8. **Orthopedics**
   a. Arthrocentesis—knee aspiration
   b. Joint injection—shoulder
   c. Joint injection—knee
   d. Trigger point injection
   e. Lateral epicondyle injection
9. **Gastroenterology**
   a. Anoscopy
   b. Flexible sigmoidoscopy
   c. Internal hemorrhoid banding
   d. External hemorrhoid excision
   e. Nasogastric intubation
10. **Gynecology**
    a. Pap smear
    b. Bartholin's marsupialization
    c. Bartholin's cyst Word catheter placement
    d. Vulvar biopsy
11. **Inpatient medicine**
    a. Lumbar puncture
    b. Subclavian lines
    c. Thoracentesis
    d. Abdominal paracentesis
12. **Obstetrics**
    a. Vaginal delivery
    b. Episiotomy-laceration repair
13. **Reproductive—female**
    a. Intrauterine device (IUD) insertion
    b. IUD removal
    c. Diaphragm insertion
14. **Urinary**
    a. Bladder catheterization—female
    b. Bladder catheterization—male

1. ANESTHESIA

A. LOCAL ANESTHESIA

Key Steps

1. Select anesthetic and needle.
2. Provide countertraction.
3. Infiltrate underneath entire lesion.
4. Use field block technique.

INSTRUCTIONS

1. Perform local anesthesia with either direct infiltration or a field block.
2. Block smaller lesions with direct infiltration.
3. Excellent anesthesia may be provided with 1% lidocaine with or without epinephrine.
4. Injection using a 27- or 30-gauge needle is well tolerated.
5. Buffering the lidocaine with bicarbonate suspension reduces the burning associated with infiltration.
6. Applying countertraction to the skin allows for more precise injection into the subcutaneous and dermal layers.
7. Depending on the type of incision, extend the area of infiltration at least 2 to 3 mm beyond the incision that has been planned.
8. Often the area needs several injections for a full block.
9. Perform field blocks by injecting widely around the lesion in a diamond-shaped pattern.

Text adapted from Tuggy ML, Garcia J, Newkirk GR (eds): *Pocket procedures* text in *Multimedia primary care procedures,* Philadelphia, 2006, Saunders. Illustrations from Rosen R, Chan TC, Vilke GM, Sternbach G: *Atlas of emergency procedures,* St Louis, 2001, Mosby.

10. Pass the needle at 60-degree angles from one side of the lesion.
11. Perform the same needle passes on the opposite side to completely surround the area with anesthesia.
12. Perform a deep injection below the lesion to ensure that the block is complete in the center of the area.

INDICATIONS
- Pain relief for procedures
- Pain relief for trauma or for joint or fracture injection
- Adjunctive pain relief for steroid injection
- Diagnostic to assess origin of pain

CONTRAINDICATIONS
- Injecting into a sterile space through superficially infected area
- Attempting to anesthetize areas that are large enough that potential toxicity may occur

CPT AND ICD-9 CODES
No appropriate codes

B. TOPICAL ANESTHESIA

Key Steps

1. Cleanse area with alcohol.
2. Apply topical anesthetic.
3. Cover with occlusive dressing.
4. Remove cover in 30 minutes to 2 hours.

INSTRUCTIONS
1. To obtain topical anesthesia of the skin, first wipe the skin with alcohol to remove the surface oils.
2. Apply the topical anesthetic cream to the planned incision area.
3. Use 1 to 2 grams of cream to cover a 3-by-3-cm area.
4. Cover the area with an occlusive dressing for 30 to 120 minutes depending on the topical agent that is chosen and the desired depth of anesthesia.
5. At 30 to 60 minutes, 3-mm depth is usually anesthetized, with an additional 1-mm depth added for every 30 minutes up to 120 minutes total application time.
6. Remove the dressing and perform the procedure.
7. The skin should show some blanching in the area that is anesthetized.
8. For topical anesthesia for mucous membranes, use topical spray lidocaine or benzocaine.
9. Apply the spray; onset of action is under 3 minutes.
10. Start the procedure at that time.

C. DIGITAL BLOCK

Key Steps

1. Cleanse digit with antiseptic.
2. Inject local anesthesia without epinephrine.
3. Inject at 9 to 10 o'clock and at 2 to 3 o'clock.
4. Secondary injections.

INSTRUCTIONS
1. Perform digital blocks by injecting plain lidocaine alongside the base of the digit from 9 to 10 o'clock and from 2 to 3 o'clock to anesthetize the digital nerves.
2. Approximately 1 ml of lidocaine is sufficient to provide adequate anesthesia.
3. In some patients, injecting lidocaine toward the palmar surface may be necessary to obtain complete anesthesia of the digit.
4. In some instances, as with nail removal, a simple tourniquet from a latex drain may be used to minimize bleeding in the field and retain the injected anesthesia agent in vascular digits.

INDICATIONS
- Need for local anesthetic that encompasses the digit
- Ingrown nail removal
- Drainage of felon or paronychia
- Management of fracture of phalanx

CONTRAINDICATIONS
- Use of epinephrine in the anesthetic is contraindicated
- Patient with hypotension or sepsis leading to peripheral vasoconstriction
- Coagulation defect (either medication related, congenital, or acquired), relative

CPT AND ICD-9 CODES
No appropriate codes

2. BIOPSY TECHNIQUES

A. EXCISIONAL SKIN BIOPSY

Key Steps

1. Incise around lesion.
2. Excise lesion.
3. Undermine skin edges.
4. Perform deep layer closure.
5. Perform skin closure.

INSTRUCTIONS
1. Most lesions require an elliptical excision around the lesion.
2. The longitudinal axis of the ellipse should follow the skin lines.
3. Excise the skin through the dermis to obtain a full-thickness biopsy.
4. Once the ellipse is created, completely remove the tissue sample by severing the underlying subcutaneous attachments.
5. To reduce the tension on the wound while it is healing, undermine the tissue along the margins of the excision.
6. Use a subcuticular inverted mattress stitch to close the deep layer prior to placing the cutaneous stitches.
7. Two or three deep stitches are usually adequate to support the closure of small excisions.
8. Deep stitches help to control bleeding and reduce tension on the scar, allowing for improved healing.
9. Perform skin closure using nylon suture material that is appropriate for the size of the lesion and location on the body.
10. Place simple interrupted sutures to bring the wound edges together to allow healing with minimal scarring.
11. Nylon stitches are nonabsorbable and require removal in 5 to 10 days depending on the site.
12. Send the specimen for pathologic review.

INDICATIONS
- Skin lesions that appear to be malignant; it is especially important to leave 1- to 2-mm margins beyond the lesion if attempting to cure
- Nevi of uncertain malignant potential—acquired, dysplastic, or atypical in appearance
- Benign growths that cause local irritation (pyogenic granulomas, dermatofibromas)
- Removal of subcutaneous growths (sebaceous cysts, lipomas)

CONTRAINDICATIONS
- Local infection at the site of planned biopsy
- Coagulation defect (either medication related, congenital, or acquired)
- Nonexcisional treatment option available and not yet tried
- Patient who is unable to comply with wound care

B. PUNCH BIOPSY

Key Steps

1. Cleanse skin and inject local anesthesia.
2. Perform punch biopsy of lesion.
3. Sever base of punch.
4. Suture or topical hemostasis.

INSTRUCTIONS

1. The punch biopsy allows for a full-depth diagnostic sample to be taken from a lesion in a short period of time.
2. Clean the area with Betadine solution. (First check for iodine allergy.)
3. Then inject 1% lidocaine local anesthetic under the lesion.
4. Here use the 2-mm punch biopsy to create a small plug of tissue that you will excise.
5. Use a pair of Adson's forceps to lift the plug, and use iris scissors to sever the base.
6. Cauterize the open punch with ferrous subsulfate solution (Monsel's solution) on a cotton wick or swab.
7. Punch biopsy sites larger than 3 mm often require stitch closure on keratinized skin or any site where cosmetic result is more critical, such as the face.

INDICATIONS

- Skin lesions that appear to be malignant where diagnosis will affect excision of the lesion
- Nevi of uncertain malignant potential: acquired, dysplastic, or atypical in appearance
- Rashes where diagnosis is unclear
- Removal of a small lipoma, which usually requires a large punch biopsy (5 to 6 mm)

CONTRAINDICATIONS

- Local infection at the site of planned biopsy
- Coagulation defect (either medication related, congenital, or acquired)
- Nonexcisional treatment option available and not yet tried
- Patient who is unable to comply with wound care

C. SHAVE BIOPSY

Key Steps

1. Cleanse skin.
2. Apply local anesthesia.
3. Shave lesion.
4. Topical hemostasis.

INSTRUCTIONS

1. Perform the shave biopsy in a clean manner, as complete sterile technique is not required for superficial lesions.
2. First, clean the skin with the antiseptic solution.
3. Then inject 1% lidocaine to create a wheal at the base of the lesion.
4. Whether or not epinephrine is used depends on the anatomic location of the lesion that is to be biopsied.
5. Once the lesion has been anesthetized, use a pair of pickups with teeth to raise the lesion and use a 15 blade to shave the lesion off at the dermis.
6. To obtain hemostasis, use ferrous subsulfate solution (Monsel's solution) to chemically cauterize the base of the lesion.
7. Use a simple adhesive bandage to cover the biopsy site.
8. The procedure is now complete.

INDICATIONS

- Skin lesions that appear to be benign where cosmetic removal is important
- Nevi of uncertain malignant potential: acquired, dysplastic, or atypical in appearance; complete excision would be required if the lesion is malignant
- Rashes where diagnosis is unclear
- Removal of a small lipoma, usually requiring a large punch biopsy (5 to 6 mm)
- For diagnosis of potential malignant lesions where punch biopsy is not feasible owing to location

CONTRAINDICATIONS

- Local infection at the site of planned biopsy
- Coagulation defect (either medication related, congenital, or acquired)
- Nonexcisional treatment option available and not yet tried
- Patient who is unable to comply with wound care

3. SUTURES AND DRESSINGS

A. INSTRUMENT TIE

Key Steps

1. Initiate tie with surgeon's knot.
2. Tighten knot so that it lies flat.
3. Perform second throw in opposite direction.
4. Perform two additional throws to secure knot.

INSTRUCTIONS

1. Initiate the instrument tie with a surgeon's knot.
2. Perform it by wrapping the suture around the needle holder twice before grasping the other end of suture and closing the knot.
3. When the first tie is completed, perform the next wrap of the suture in the opposite direction around the needle holder.
4. Now the knot is locked.
5. Perform two or more separate throws to secure the knot in place.
6. Alternating knot throws in different directions prevents premature unraveling of the knot.

INDICATIONS

- Low-tension wound closures
- Deep closure in confined wound space where manual ties would be difficult

CONTRAINDICATIONS

- Knots requiring significant tension or sutures applied for hemostasis

B. INVERTED SUBCUTICULAR STITCHES

Key Steps

1. Initial stitch enters deep.
2. Second stitch enters superficially.
3. Tie knot in subcutaneous layer.
4. Repeat for each stitch.

INSTRUCTIONS

1. Use inverted stitches to close deep layers of a wound and allow the knot to be buried in the process.
2. The needle tip enters the deeper layer of the subcutaneous tissue and is then brought upward so that it exits the same side more superficially, often in the subcuticular layer.
3. Bring the needle to the other side of the wound so that it enters in the superficial aspect of the wound at the same level as the first side.
4. Drive the needle deep so that it exits the tissue deep in the wound space where the stitch started.
5. Once that is done, tie the knot.
6. During the tightening of the knot, pull the wound together with the knot lying deep to the subcuticular layers that are brought together by the stitch.
7. Cut the suture short and apply the next stitch elsewhere in the wound to bring about further closure of the wound.
8. For small wounds, one or two inverted knots will close the deep layers well.

INDICATIONS
- High-tension wound closures that require deep-layer closure where knots are preferably buried
- Wound closures where external suture punctures would be cosmetically unfavorable
- Wounds that require prolonged support for optimal closure
- Adjunctive closure with subcuticular running stitches

CONTRAINDICATIONS
- Knots requiring significant tension or sutures applied for hemostasis

CPT AND ICD-9 CODES
No appropriate codes

C. SUBCUTICULAR RUNNING STITCHES

Key Steps

1. Make linear incision under minimal tension.
2. Running suture with knot at each end.
3. Reinforce with Steri-strips or tissue glue.

INSTRUCTIONS
1. Bury subcuticular sutures running horizontal sutures.
2. This technique is useful for wounds that are under minimal tension and in which cosmetic results are important.
3. It is possible to close deeper wounds with deep sutures of subcutaneous sutures first.
4. Begin with a knot beyond one apex of the incision, using polypropylene-coated nylon suture.
5. Place the needle through the skin to emerge in the wound.
6. Run the suture, taking horizontal bites through the superficial papillary dermis, alternating sides so that the exit point of one side matches the entry point of the other.
7. Keep the suture under minimal tension.
8. Emerge at the other end beyond the apex and place a second knot.
9. Reinforce the wound with Steri-strips or tissue glue.

INDICATIONS
- Low-tension to moderate-tension wound closures that follow skin lines or wounds partially closed by deeps sutures to support the skin closure
- Wound closures where external suture punctures would be cosmetically unfavorable
- Wounds that require prolonged support for optimal closure

CONTRAINDICATIONS
- Knots requiring significant tension or sutures applied for hemostasis

CPT AND ICD-9 CODES
No appropriate codes

D. MATTRESS STITCHES

Key Steps

1. Deeply insert needle 0.5 to 1 cm from wound edge.
2. Pass needle deeply across the base of wound.
3. Exit opposite side at same distance.
4. Reinsert at 0.3 cm from edge on same side of wound.
5. Cross wound, exit at same shallow depth, and tie knot.

INSTRUCTIONS
1. Mattress sutures are useful in wounds that are under high or moderate tension and where eversion of wound edges is desired.
2. Vertical mattress sutures are initially a simple deep interrupted suture, with the needle penetrating the skin 0.5 to 1 cm from the wound edge, depending on the location and size of the wound (Fig. AII-1, *A*).
3. Track the suture needle across the wound to 75% of the wound depth, and emerge from the opposite side at the same distance from the skin.
4. Reinsert the needle closer to the wound edge, 0.5 to 0.3 cm from the wound, and to 25% of the wound depth, emerging from the opposite side at the same distance from the wound edge.

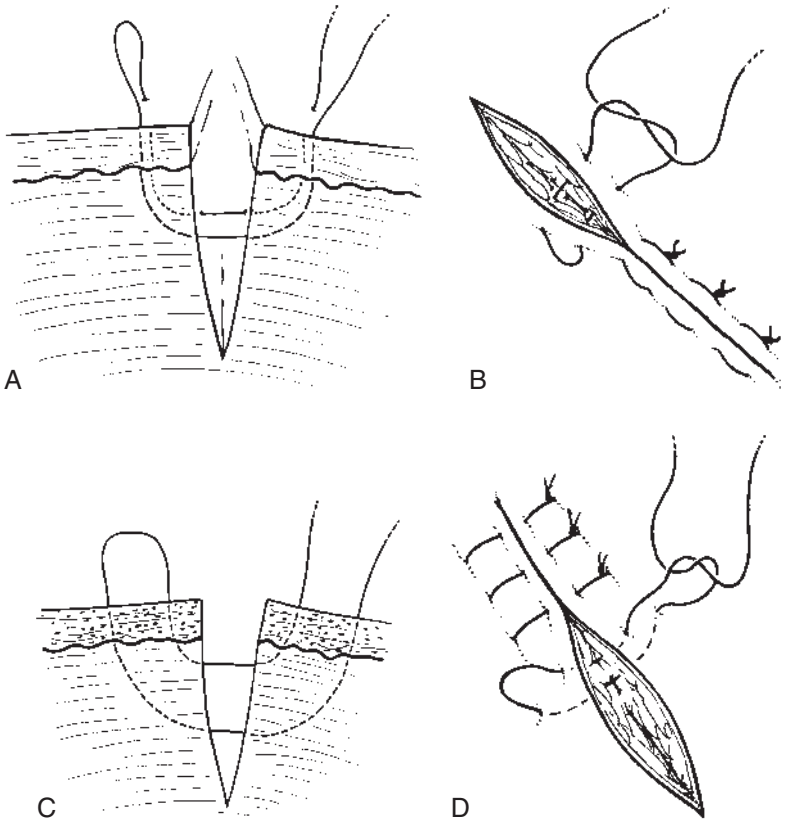

FIGURE AII-1 Mattress stitches.

5. Tie the knot, keeping the suture in sufficient tension to close the wound but not strangulate the tissue (Fig. All-1, *B*).
6. Repeat knots about 0.5 to 1 cm apart to close the wound (Fig. All-1, *C* and *D*).
7. These sutures risk producing cosmetically undesirable marks if left in too long and should be evaluated for removal at 1 week or less, depending on the site.

INDICATIONS
- Moderate-tension to high-tension wounds
- Wound closures where external suture punctures would be cosmetically tolerated
- Wounds that require prolonged support for optimal closure
- Wounds in areas where inversion of wound edges is more likely (chest, shoulder, thigh)

CONTRAINDICATIONS
- Wound closures where external suture punctures would be cosmetically unfavorable
- Cosmetically sensitive areas where the eversion of the wound may lead to thickened scar

CPT AND ICD-9 CODES
No appropriate codes

E. TISSUE GLUE

Key Steps

1. Identify appropriate wound type.
2. Cleanse and dry wound area.
3. Apply three or four layers of tissue glue.
4. Dry between each layer to bond skin edges.

INSTRUCTIONS
1. Tissue glues are useful for low-tension wound closures or for small wounds that need closure for improved hemostasis.
2. First, irrigate, clean, and dry the wound.
3. Crush the applicator ampule and allow the adhesive to fill the tip.
4. Pinch the wound shut and apply the glue to the surface in three or four layers, allowing for drying between each layer.
5. Take care to avoid gluing any unwanted materials or personnel to the patient.
6. Once the glue is dry, you may cover the wound or leave it open depending on the site and risk of contamination.

INDICATIONS
- Superficial lacerations
- Nail lacerations
- Superficial closure over deeper tension-reducing sutures
- Repair of lacerated nails or nail beds

CONTRAINDICATIONS
- Mucosal lesions
- Wounds under tension
- Contaminated lesions
- Puncture wounds and crush wounds
- Bite wounds
- Complex lacerations
- Lacerations in the axilla

CPT AND ICD-9 CODES
Codes are dependent on lesion size and location

F. TOPICAL HEMOSTASIS

Key Steps

1. Perform electrocautery.
2. Silver nitrate may be used.
3. Ferrous subsulfate solution (Monsel's solution) may be used.

INSTRUCTIONS
1. Obtain a topical hemostasis in several ways.
2. Use the Hyfrecator or radiofrequency device to cauterize or coagulate the base of superficial or deep excisions.
3. Silver nitrate sticks are useful for cauterizing superficial lesions, though they may leave a stain in the dermal layer.
4. Ferrous subsulfate solution is an effective topical agent that leaves little residue after its application and is ideal on mucous membranes such as the cervix, vagina, vulva, and penis.

INDICATIONS
- For bleeding after cutaneous surgery, especially partial-thickness shave or curetted biopsies
- To treat nail beds after full or partial nail removal
- To treat mucous membrane biopsy sites of the glans penis, vulva, vagina, and cervix

CONTRAINDICATIONS
- Allergy to topical agent
- Heavy bleeding, in which case the agent is usually not effective

G. UNNA BOOT APPLICATION

Key Steps

1. Apply moistened Unna boot wrap.
2. Wrap second layer with elastic wrap.
3. Ensure that ankle is at 90 degrees.

INSTRUCTIONS
1. Apply the Unna boot in a manner similar to the application of a cast to the lower leg. The Unna boot is much simpler, however, because it requires only two layers.
2. Place the Unna boot material directly against the skin, wrapping it on the leg.
3. If there are open ulcers or lesions on the foot or lower leg, ensure that the Unna boot covers them well.
4. In areas where there are excess amounts of the wrap owing to changes in the wrapping angle, simply fold in the Unna boot material to allow for compensation of these excess segments of the wrap.
5. Once the Unna boot is applied, wrap a second layer around the entire Unna boot to secure it.
6. Use an elastic wrap material for the second layer.
7. Position the ankle at 90 degrees at the conclusion of wrapping.
8. The Unna boot will dry slowly over the next 24 hours and provide an occlusive dressing to the lower leg and foot that can be left in place for 5 to 7 days.

INDICATIONS
- Venous stasis ulcers
- Post–venous thrombosis ulcers
- Severe lower-extremity edema with impending ulceration

CONTRAINDICATIONS
- Current venous thrombosis
- Current arterial disease
- Infected ulcers
- Cellulitis
- Allergy to components of the Unna boot

CPT CODES
29580 Unna boot application

ICD-9 CODES
457.1 Lymphedema
707.12 Decubitus ulcers, calf
707.13 Decubitus ulcers, ankle

4. NEEDLE ASPIRATION

A. BREAST CYST ASPIRATION

Key Steps

1. Cleanse skin and palpate nodule.
2. Insert aspiration needle.
3. Multiple passes into nodule.
4. Apply pressure to site.
5. Place aspirate on slide.

INSTRUCTIONS

1. The breast nodule is identified by palpation, and the skin is prepped with antiseptic solution.
2. Fix the cyst to the chest wall between the operator's fingers.
3. Place the needle into the center of the cyst, and then withdraw the plunger to allow for creation of a vacuum.
4. Larger fluid samples can be sent directly to the pathologist.
5. If only a small volume of fluid is obtained, express the contents of the syringe onto a slide and fix with cytology fixative.
6. A second pass may be performed to gather more material for sampling.
7. Apply pressure to the needle insertion site to prevent hematoma formation.
8. Spray the contents of the syringe onto a slide.
9. Use a second slide to gently layer the specimen.
10. Spray cytology fixative onto the slide to prevent drying before fixation.
11. Send the specimen to the laboratory for cytology analysis.

INDICATIONS

- Palpable lump in the breast
- Treatment of breast cyst
- Abnormal mammographic findings combine with stereotactic location of biopsy site

CONTRAINDICATIONS

- Poorly controlled infection over needle site
- Known malignancy (excisional surgery indicated)

CPT CODES

88170 Fine needle aspirate (FNA) with or without preparation of smears
19100 Biopsy of breast, needle (FNA)

ICD-9 CODES

611.72 Lump or mass in the breast
217 Benign neoplasm of the breast
174.9 Malignant neoplasm of breast (female) unspecified

5. DERMATOLOGY

A. SKIN TAG REMOVAL

Key Steps

1. Inject local anesthesia beneath tag.
2. Make a sharp excision.
3. Cauterize.

INSTRUCTIONS

1. Wipe the skin with antiseptic solution.
2. Treat skin tags with or without anesthesia depending on patient preference and the size of the tag to be removed.
3. Make a small wheal of local anesthetic under each skin tag.
4. Grasp the skin tag with a forceps and trim it at the base with iris scissors.
5. Cauterize the base of the skin tag with either electrical or chemical cautery methods.

INDICATIONS

- Symptomatic skin tags in areas of frequent microtrauma, such as the neck line or axilla
- Diagnostic concerns (diagnostic removal)
- Cosmetic concerns

CONTRAINDICATIONS

- Local skin infection
- Concern for uncontrollable cosmetic result

CPT CODES

11200 Skin tag removal by excision or destruction 1-15
11201 Each additional tag, up to 10, or portion thereof

ICD-9 CODES

701.9 Skin tags

B. WART TREATMENT

Key Steps

1. Perform cryotherapy: 1-second to 3-second freeze.
2. Refreeze lesions.
3. Use electrocautery method.

INSTRUCTIONS

1. Several options may be used to treat warts.
2. Cryotherapy offers a rapid method of treatment of superficial warts.
3. Cryotherapy is usually effective if the warts are small and the patient either returns for follow-up or continues to use topical medications after the initial treatment.
4. Perform cryotherapy using either a cotton swab dipped in liquid nitrogen and applied to the wart or a liquid nitrogen container equipped with a spray tip to apply the liquid nitrogen directly to the wart.
5. Spray each wart until the entire wart and a 1-mm margin have frozen to form a white disc.
6. Allow this to thaw, and then refreeze it.
7. This dual freeze cycle ensures necrosis of the frozen area.
8. Wart cryotherapy also may be done with a nitrous oxide cryotherapy unit fitted with a dermal tip.
9. Often, paring the wart down to skin level improves success with cryotherapy.
10. For persistent or recurrent warts that fail cryotherapy, injecting local anesthetic and using a Hyfrecator to ablate the lesion is an effective way to eradicate the warts.

INDICATIONS

- Painful, bleeding, or unsightly warts
- Warts failing to resolve spontaneously (up to 30% of warts disappear without treatment within 6 months)
- Warts have a negative impact on the patient's life (e.g., cosmetic issues, employment issues)
- Warts are growing or multiplying rapidly
- Patient has concerns about spreading the virus

CONTRAINDICATIONS

- Poorly controlled local infection, which should be treated prior to the procedure
- Caution in cosmetically sensitive areas such as face, lip, or eyelid

CPT CODES

17110 Destruction of warts 1-14
17111 Greater than 15 warts

ICD-9 CODES

078.19 Plantar warts
078.10 Verruca vulgaris
078.11 Condyloma acuminata

C. ABSCESS INCISION AND DRAINAGE

Key Steps

1. Wear eye protection.
2. Perform field block.
3. Open abscess with incision that follows skin lines.
4. Liberate all areas of abscess.
5. Abrade surface of abscess wall and clear debris from wound.

INSTRUCTIONS

1. Wear eye splash protection. Identify abscess (Fig. AII-2, *A*).
2. Perform a field block by inserting the needle at opposite ends of the area to be anesthetized (Fig. AII-2, *B*).
3. Pass the needle alongside the edge of this region and then withdraw it while anesthesia is injected.
4. Reinsert the needle at 60 to 90 degrees to the initial block at the adjacent aspect of the first injection.
5. After the initial half of the block is completed, anesthetize the opposite side to complete a diamond-shaped field block.

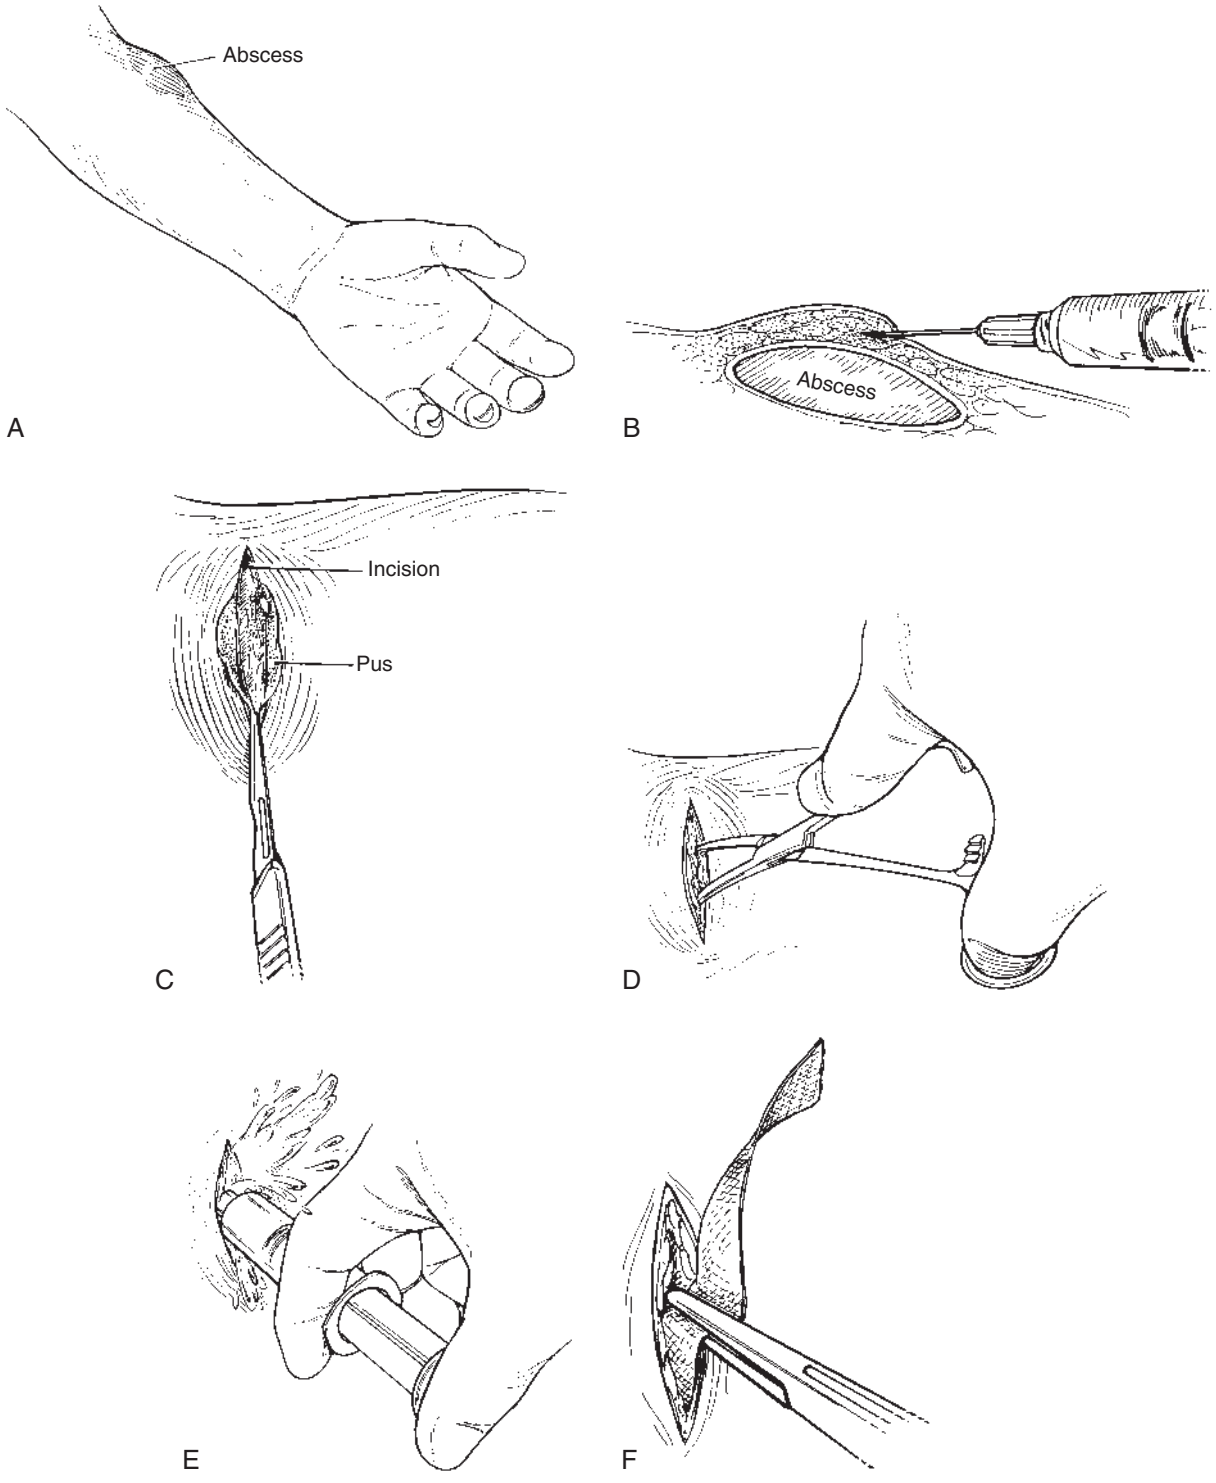

FIGURE AII-2 Abscess incision and drainage.

6. Open abscesses with an incision that follows the skin lines (Fig. All-2, *C*).
7. Use a 15 blade to open the skin and express the material inside the abscess.
8. Use hemostats to break open adhesions or abscess pockets and to ensure that all areas of the abscess are liberated (Fig. All-2, *D*). Irrigate the abscess cavity (Fig. All-2, *E*).
9. A sebaceous abscess has a smooth capsular lining that needs to be stripped out to prevent recurrence.
10. Use a curved hemostat to grasp portions of this capsule wall, which may need to be removed piecemeal.
11. In lesions that are not actively inflamed, it may be possible to dissect out the entire wall.
12. Gauze can be used to abrade the surface of the abscess wall and clear debris from within the wound.
13. After draining the abscess and removing or disrupting the sebaceous cyst wall, pack iodoform gauze into the wound and leave it in place for 2 to 3 days (Fig. All-2, *F*).
14. After 2 to 3 days, the wound can be allowed to heal by secondary intention.
15. For larger abscesses, repacking may be necessary to prevent premature closure and abscess reformation.

INDICATIONS
- Abscess formation within the cutaneous layers anywhere on the body

CONTRAINDICATIONS
- Virtually none, unless the lesion is on the face within the nasolabial triangle and can be treated with warm compresses with a high probability of spontaneous drainage

CPT CODES
10060 I&D, one abscess
10061 I&D, multiple or complex abscess

ICD-9 CODES
682.9 Cellulitis, abscess, NOS

D. BASAL CELL CURETTAGE AND CAUTERY

Key Steps

1. Mark lesion.
2. Inject local anesthesia.
3. Cycles of curettage and cautery.

INSTRUCTIONS
1. Punch biopsy of a suspicious lesion on the patient's arm confirmed basal cell carcinoma.
2. Mark the lesion with a surgical marker to clearly delineate the extent of the superficial cancer.
3. Infiltrate local anesthesia consisting of lidocaine with epinephrine under the lesion.
4. Use a curette to scrape the lesion from the skin surface down into the dermal layer.
5. As curettage is performed, the operator should be able to sense the softness of the basal cell cancer in contrast to the normal dermal layer.
6. Remove all areas of abnormal density tissue.
7. Be especially attentive to the area where the punch biopsy was performed and the prior borders from the surgical marker.
8. Curette the lesion in every direction, performing cautery between each curettage episode.
9. Generally, perform four cycles of curettage and cautery to ensure that the process eradicates any dermal extension of the basal cell cancer.
10. Cover the wound with a simple adhesive bandage on completion of the procedure.
11. Cure is assured by finding normal skin on follow-up examination.

INDICATIONS
- Seborrheic and actinic keratoses
- Basal cell carcinoma
- Squamous cell carcinoma
- Condyloma
- Pyogenic granuloma

CONTRAINDICATIONS
- Cellulitis and other bacterial infections
- Lesions that require complete excision for diagnosis or treatment
- Pacemakers with electrodesiccation

CPT AND ICD-9 CODES
Codes dependent on lesion size and location

E. LIPOMA REMOVAL

Key Steps

1. Inject anesthesia and make incision.
2. Blunt and sharp dissection.
3. Extrude lipoma.
4. Place drain.
5. Close wound.

INSTRUCTIONS
1. The majority of lipoma excisions involve small tumors approximately 3 to 5 cm in size located in the subcutaneous tissues of the trunk or extremities.
2. Occasionally in practice, one will encounter large lipomas that require excisions done in an operating suite under the general anesthesia to avoid lidocaine toxicity.
3. Place the patient under general anesthesia and situate the patient in the right lateral decubitus position.
4. Clean the skin with bactericidal solution and make an incision following the skin lines on the left lateral chest wall.
5. Use blunt dissection to expose the superficial surface of the lipoma using a hemostat to separate the layers of subcutaneous tissues that can moderately adhere to the surface of the lipoma.
6. With larger lesions, more extensive adhesions and subcutaneous fibers may prevent easy extrusion of the tumor.
7. After exposing the initial surface of the lipoma, the dissection continues, using both sharp and blunt dissection to liberate the lipoma from the connective tissue strands holding it to the chest wall.
8. Once the perimeter of the lipoma is fully palpable, use both sharp and manual dissection techniques to lift the lipoma off of the connective tissue overlying the rib cage.
9. After freeing the majority of the lipoma from the adhesions, extrude the mass out of the incision, then lift it to allow sharp dissection of the basal stalk connecting it to the rib cage.
10. Once this has been completed, inspect the wound for any active bleeding and cauterize the necessary vessels.
11. Irrigate and prepare the space for closure.
12. Prior to closing, inject Marcaine local anesthetic into the subcutaneous layer to provide anesthesia for several hours after the procedure.
13. There is significant reduction in pain with use of local anesthetic even in patients who are undergoing surgery with general anesthesia to reduce postoperative pain.
14. Place two deep sutures of 2-0 Vicryl to tack the subcutaneous layer to the connective tissue overlying the rib cage, closing the potential dead space.
15. After removal of a large tumor, place a Penrose drain to prevent accumulation of serous fluid within the potential dead space in the subcutaneous layer.
16. Then use a running subcuticular stitch to close the surface layer of skin and hold the Penrose drain in place.
17. Cover the wound with a sterile dressing and advise the patient to follow up in 48 hours.
18. At the follow-up visit, the patient should have minimal incisional pain, and you should remove the Penrose drain.

INDICATIONS
- Large, rapidly growing lipoma, where malignant degeneration is possible
- Lipomas in cosmetically sensitive areas that are visible
- Uncertain diagnosis of subcutaneous mass

CONTRAINDICATIONS
- Patient with numerous nonvisible lipomas
- Local infection at the site of planned excision
- Coagulation defect (either medication related, congenital, or acquired)
- Nonexcisional treatment option available and not yet tried
- Patient unable to comply with wound care

F. INGROWN TOENAIL REMOVAL

Key Steps

1. Anesthetize with digital block.
2. Dissect nail.
3. Excise nail.
4. Ablate nail bed.

INSTRUCTIONS
1. Adequately anesthetize the toe with a digital block.
2. Then slip a single blade of the curved iris scissors between the nail and the nail plate along the ingrown area.
3. If the nail tightly adheres to the matrix, a small hemostat can help to separate these structures.
4. Feel a perceptible give when the tip of the scissors has passed the proximal edge of the nail.
5. Once this occurs, use a pair of straight mosquito hemostats to grasp the nail.
6. With firm pressure holding the nail to the nail plate, carefully roll out the affected edge to extract the ingrown portion of the nail out of its compartment.
7. Use bandage scissors to trim off the uplifted nail edge.
8. Take care to ensure that the entire portion of the nail segment to be removed has been excised down to the nail bed.
9. Phenol ablation is the most common method used to cauterize the nail bed to prevent or retard future growth of the unwanted portion of the nail.
10. Form a small plug of cotton by trimming the cotton from the tip of swab and soaking it with phenol.
11. Insert the plug into the opening left by the excised nail edge and push it into the nail bed to cauterize the area.
12. Once the nail bed has been cauterized, remove the plug.
13. Electrosurgical probes have been developed that can ablate the matrix with excellent cosmetic results.

INDICATIONS
- Onychocryptosis (ingrown nail)
- Onychomycosis (fungal infection of nail)
- Chronic, recurrent paronychia (inflammation of the nail fold)
- Onychogryposis (deformed curved nail)
- Symptomatic granulation overgrowth of nail fold, especially if recurrent
- Permanently deformed nails after trauma; nail matrix ablation is often performed at the same time

CONTRAINDICATIONS
- Noncooperative patient
- Unstable infection, may require pretreatment with antibiotics
- Marginal vascular status of digit; may require clarification prior to injection and surgery

CPT CODES
11730 Nail removal, partial or complete
11750 Permanent nail removal (matrixectomy), partial or complete

ICD-9 CODES
703.0 Ingrown toenail
110.1 Onychomycosis

6. EYE, EARS, NOSE, THROAT

A. NASOPHARYNGOSCOPY

Key Steps

1. Apply decongestant and inspect nares.
2. Apply topical anesthesia.
3. Insert into nasopharynx.
4. Inspect larynx.
5. Withdraw scope.

INSTRUCTIONS
1. The nasopharyngoscope allows the physician to visualize the upper airway precisely in patients who have upper airway complaints.
2. For right-hand-dominant persons, the base of the scope with the direction level is held in the right hand, allowing manipulation of the level by the thumb. The dial on the underside of the scope allows for upward and downward movement of the tip of the scope.
3. This movement, combined with rotation of the scope, allows for 360-degree viewing of the airway.
4. Apply a topical decongestant to allow the nares to open.
5. Inspect the nares to determine which side of the nose is the most patent to pass the nasopharyngoscope through for the examination.
6. Use the tripod technique to hold the nasopharyngoscope on the face while inserting into the nares to avoid any undue trauma.
7. Identify the nasal passage along the floor of the nose, where the scope should be passed to enter the nasopharynx.
8. To prepare for the scope insertion, spray the nares with a decongestant solution.
9. Then anesthetize the throat with a topical anesthetic, followed by application of the anesthetic into the selected side of the nose for scope passage.
10. First, spray the anterior aspect of the nares, then insert the spray tip perpendicular to the plane of the face along the floor of the nose.
11. As the patient holds his or her breath, apply the anesthetic to the deep aspect of the nose as the tip is withdrawn.
12. Now advance the nasopharyngoscope into the nares and along the floor of the nasal passage.
13. The initial structures that are encountered are the palatine tonsils.
14. Rotation of the tip of the scope with flexion laterally to approximately 90 degrees allows one to visualize the Eustachian tube openings and Rosenmüller's fossa.
15. After inspection of these surfaces, advance the scope down into the oropharynx.
16. The key structures of the oropharynx to inspect are the base of the tongue, the vallecula, and the posterior aspect of the tonsils.
17. Having a patient extend the tongue out of the mouth allows one to visualize the vallecula.
18. After inspecting the oropharynx, advance the scope into the hypopharynx, where one visualizes the laryngeal structures and vocal cords.
19. Here, inspect the true cords and false cords and the overlying soft tissue of the laryngeal cartilage.
20. Also inspect the pyriform sinuses on either side of the larynx.
21. The vocal cord movement and symmetry are important to document.
22. One can see clearly the movement of the arytenoid cartilage as the vocal cords are contracted.
23. On finishing the complete inspection, withdraw the scope in neutral position.

INDICATIONS
- Epistaxis
- Removal of foreign body
- Chronic rhinorrhea
- Chronic cough evaluation
- Dysphagia
- Chronic or recurrent sinusitis evaluation
- Snoring
- Dysphonia

CONTRAINDICATIONS
- Epiglottitis
- Profuse epistaxis

CPT CODES
31231 Nasopharyngoscopy

IDC-9 CODES
472.0 Rhinitis
473.9 Sinusitis, chronic

B. CERUMEN IMPACTION REMOVAL

Key Steps

1. Examine ear canal.
2. Select device for irrigation.
3. Irrigate until cerumen is released.
4. Conduct follow-up examination.

INSTRUCTIONS
1. To remove impacted cerumen, one can use a pulsating water device that allows for pressurized water flow to enter the ear canal.
2. Inject the water along the sidewall of the ear, gently forcing water around the impacted cerumen.
3. Within a few minutes, one can see small fragments of cerumen coming from the ear canal.
4. After several minutes of irrigation, the bulk of the cerumen plug is removed.
5. Other device options include a 20- to 30-ml syringe with a 16- to 20-gauge IV catheter attached to provide directed water flow into the ear canal.
6. Examine the ear after irrigation to ensure that adequate cerumen was removed.

INDICATIONS
- Cerumen impaction

CONTRAINDICATIONS
- Tympanic membrane perforation

CPT CODES
69210 Cerumen removal

ICD-9 CODES
380.4 Cerumen impaction

7. HAND/DIGIT

A. RING REMOVAL

Key Steps

1. Perform neurovascular examination.
2. Insert tape with hemostat.
3. Wind tape proximal to distal.
4. Do not compromise arterial supply.
5. Pull proximal edge to unwind.

INSTRUCTIONS
1. After careful neurovascular exam demonstrates intact sensation and arterial supply, lubricate the finger (Fig. AII-3, *A*).
2. Carefully insert spooled suture, umbilical tape, or dental floss under the palmar aspect of the ring with a hemostat (Fig. AII-3, *B*).
3. Secure the suture edge to the palm with an adhesive.
4. Proceed to wrap the suture firmly around the finger, starting immediately distal to the ring and moving distally.
5. Wrap the suture tightly enough to compress the edema without producing any arterial compromise (Fig. AII-3, *C*).
6. After relubricating the finger and removing the suture, gently unwind the proximal edge of the suture by pulling distally and circumferentially (Fig. AII-3, *D* and *E*).
7. After removing the ring, repeat the neurovascular exam.

INDICATIONS
- Distal finger injury with impending swelling of the finger
- Ring finger with signs of vascular compromise due to compression from the ring
- Ring made of conductive or magnetic metal in patient undergoing procedure in which such objects pose a threat to the patient or staff

CONTRAINDICATIONS
- Extensive bony injury or swelling where it is clear that cutting the ring is the only option

CPT CODES
20670 Superficial removal of constricting metal band
20680 Deep removal of constricting metal band

ICD-9 CODES
782.3 Traumatic edema

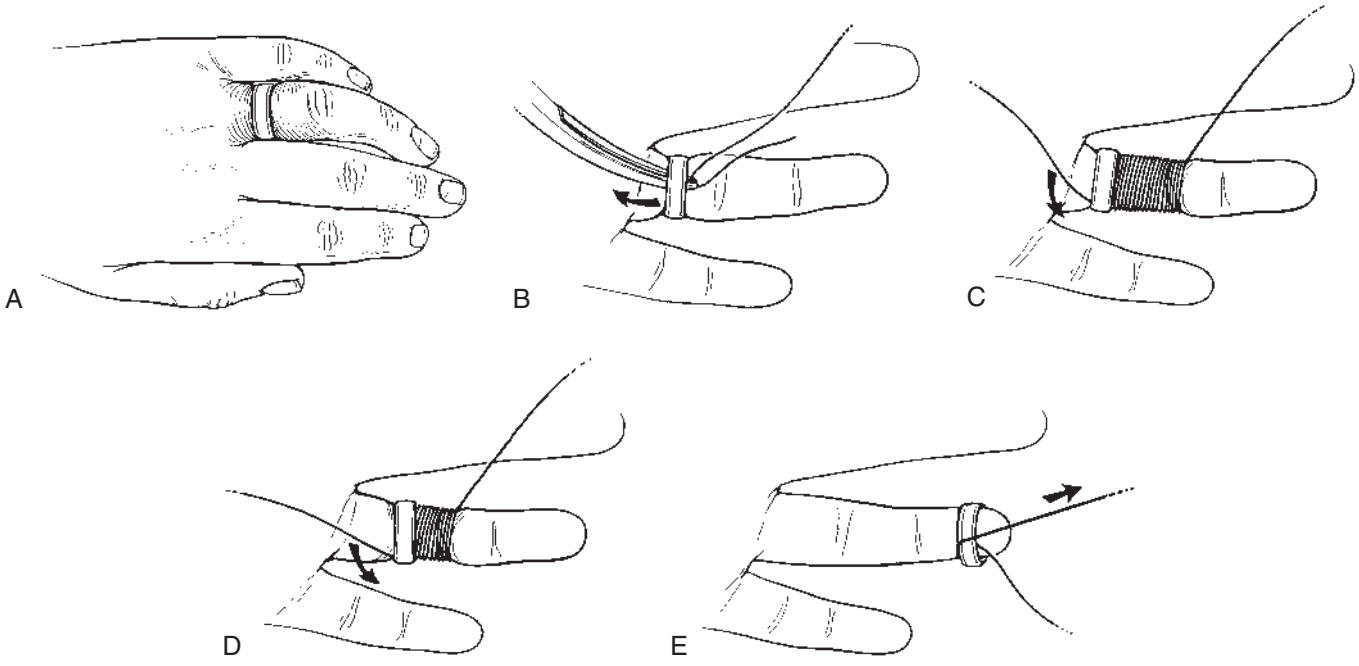

FIGURE AII-3 Ring removal.

8. ORTHOPEDICS

A. ARTHROCENTESIS—KNEE ASPIRATION

Key Steps

1. Determine best access to effusion.
2. Cleanse skin.
3. Inject local anesthesia at insertion site.
4. Insert needle and aspirate.

INSTRUCTIONS

1. The patient is placed in the supine position.
2. The patient's knee is placed in extension (Fig. AII-4, *A*).
3. Carefully clean the skin with an antiseptic solution.
4. Identify the patella and palpate to determine the effusion size.
5. The ideal location to enter the synovial sac is in the upper outer quadrant of the knee joint space.
6. Local anesthetic injected along the planned trajectory of the arthrocentesis reduces the pain of passing the 18-gauge needle through the joint sac.
7. Pass the needle through the skin and into the palpable effusion.
8. Compress the medial aspect of the knee joint with the opposite hand to push the intraarticular fluid toward the needle and to stabilize the skin for penetration by the needle (Fig. AII-4, *B*).
9. Once the fluid space is entered, obtain a sample for diagnostic purposes.
10. For tense effusions, withdrawing larger volumes of fluid—up to 50 ml at a time—can reduce pain and improve range of motion.
11. After obtaining the desired amount of fluid, withdraw the needle and cover the entry wound.

INDICATIONS

- Acute joint effusion
- Acute joint infection
- Joint pain secondary to large effusion (acute or chronic): therapeutic
- Gout

CONTRAINDICATIONS

- Local skin infection at the site of joint
- Local bursa infection overlying joint
- Coagulation defect (either medication related, congenital, or acquired), relative
- Artificial joint
- Immunosuppressed patient with noninfected joint
- Sepsis or bacteremia not coming from the joint
- Unstable joint

CPT CODES

20610 Arthrocentesis of the knee

ICD-9 CODES

274.0 Gouty arthropathy
715.16 DJD knee
719.45 Knee pain

B. JOINT INJECTION—SHOULDER

Key Steps

1. Determine injection site.
2. Cleanse skin.
3. Withdraw joint fluid if effusion present.
4. Inject steroid and anesthetic solution.

INSTRUCTIONS

1. Cleanse the area over the acromion and upper deltoid to prepare for the injection.
2. Maintain sterility during the injection process.
3. Identify the space between the acromion and the humerus that is covered by the proximal deltoid attachments.
4. Inject local anesthetic in a wheal on the skin, then deeply along the planned injection path into the subacromial bursa.
5. Draw up 20 mg of methylprednisolone or its equivalent into a 3-ml syringe and mix with 1 to 2 ml of anesthetic solution.
6. Use a 25-gauge needle for injection of the steroid solution.

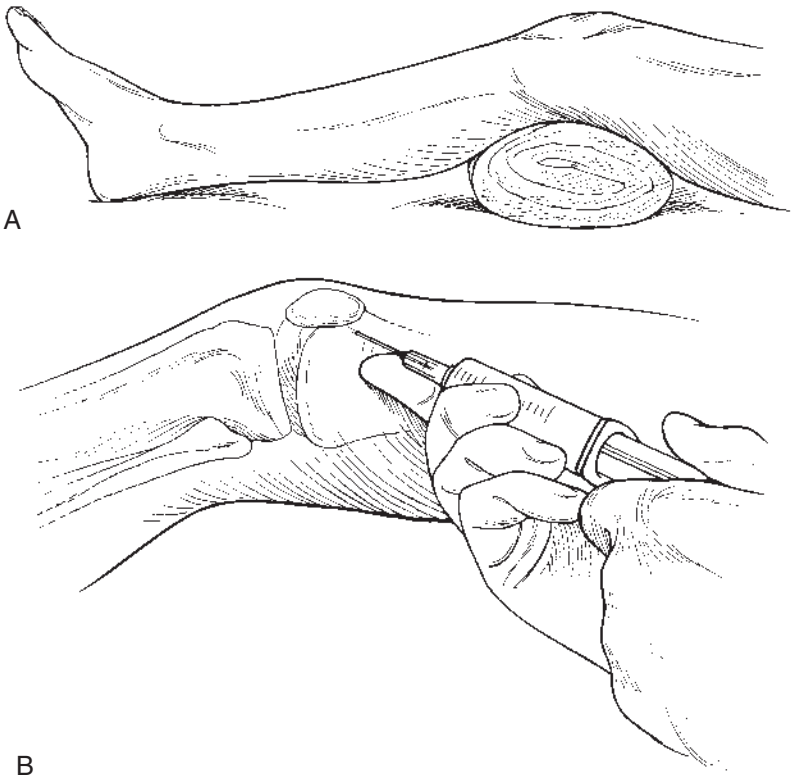

FIGURE AII-4 Knee aspiration.

7. Insert the needle into the subacromial space.
8. Inject the entire volume of the syringe into the joint space.
9. Withdraw the needle and cover the site with a simple adhesive bandage.

INDICATIONS
- Tendinitis
- Bursitis
- Rheumatoid arthritis
- Osteoarthritis
- Gout and pseudogout
- Medical conditions with joint manifestations: inflammatory bowel disease, psoriasis, Reiter's syndrome (unless associated with human immunodeficiency virus [HIV]), and ankylosing spondylitis
- Ineffective anti-inflammatory drugs and analgesics

CONTRAINDICATIONS
- Acute trauma or fracture
- Metastatic cancer
- Cellulitis over the injection site
- Septic periarticular bursa
- Suspected bacteremia unless the joint is the suspected source
- Broken skin over the injection point
- Primary coagulopathy
- Unstable joints (for steroid injection)
- Joint prosthesis
- Anticoagulant therapy
- Lack of response to two or three prior injections

CPT CODES
20610 Arthrocentesis of shoulder

ICD-9 CODES
274.0 Gouty arthritis
716.91 Arthropathy of shoulder
727.3 Bursitis, unspecified

C. JOINT INJECTION—KNEE

Key Steps

1. Determine injection site.
2. Cleanse skin.
3. Inject local anesthesia.
4. Inject steroid solution.

INSTRUCTIONS
1. Place the patient in the supine position and place the patient's knee in extension.
2. Carefully clean the skin over the upper outer quadrant with an antiseptic solution.
3. Identify the patella and determine the effusion size by palpation.
4. The ideal location to enter the synovial sac is in the upper lateral quadrant of the knee joint space, just above the patella.
5. Mix a solution of steroid, such as 40 mg of methylprednisolone, with bupivacaine to provide short-term anesthesia within the joint space.
6. Pass the needle through the skin and into the joint space.
7. With the opposite hand, compress the medial aspect of the knee joint to push the intraarticular fluid toward the needle.
8. Drain or partially drain any hemorrhagic effusion that is found.
9. After draining the fluid, inject the steroid solution.
10. Withdraw the needle and apply pressure to the site.
11. Cover the injection site with a simple bandage.

INDICATIONS
- To rule out septic arthritis
- To rule out crystal or rheumatoid arthritis
- Removal of excessive synovial fluid
- Diagnostic injection of analgesic
- Therapeutic injection of corticosteroid

CONTRAINDICATIONS
- Bleeding disorder or excessive anticoagulation
- Superficial infection or cellulites

CPT CODES
20610 Injection of joint
May also charge for office visit

ICD-9 CODES
719.45 Knee pain

D. TRIGGER POINT INJECTION

Key Steps

1. Isolate trigger point by palpation.
2. Cleanse skin.
3. Inject trigger point area.
4. Local massage to disseminate injection.

INSTRUCTIONS
1. Easily inject painful trigger points with a combination of local anesthetics and steroids to obtain immediate and long-term pain relief.
2. Mix 1 ml of bupivacaine with 1.5 ml of lidocaine and the equivalent of 25 mg of hydrocortisone to make up a solution for this injection.
3. Precisely identify the trigger point.
4. Prep the skin with Betadine or alcohol. (First check for iodine allergy.)
5. Insert the needle into the palpable trigger point.
6. Inject the solution in 0.5-ml amounts spread over the region that encompasses the entire trigger point area.
7. After completing the injection, massage the solution into the surrounding soft tissue.
8. Obtain immediate feedback from the patient as the local anesthetics takes effect.

INDICATIONS
- Myofascial pain
- Tension headache due to cervical muscle strain
- Chronic neck or back pain due to trigger points
- Fibromyalgia

CONTRAINDICATIONS
- Infection at site of trigger point
- Bleeding disorder
- Allergy to any component of injection

CPT CODES
20522 Inject trigger point, one or two sites
20553 Inject trigger points, more than two sites

ICD-9 CODES
729.1 Fibromyalgia

E. LATERAL EPICONDYLE INJECTION

Key Steps

1. Identify focal tenderness over epicondyle.
2. Cleanse skin with antiseptic.
3. Inject steroid/anesthetic solution.
4. Massage injection site.

INSTRUCTIONS
1. Place the elbow in flexion and palpate the focally tender area over the lateral epicondyle.
2. Site of maximal inflammation should be at the proximal attachment of the extensor tendons of the forearm.
3. Cleanse the skin over the epicondyle with an antiseptic solution, maintaining sterility of the injection site.
4. The injection should contain 10 mg of triamcinolone acetate or its equivalent, with 0.5 ml of lidocaine and 0.5 ml of bupivacaine.
5. Insert the needle down to the bony surface of the epicondyle, then withdraw it back 1 to 2 mm.
6. Inject the solution into the area of maximal tenderness and reposition the needle slightly in all directions around this area to distribute the medication into a 1.5- to-2-cm diameter area.

7. Withdraw the needle and massage the area.
8. Cover the site with an adhesive bandage if there is bleeding from the injection.

INDICATIONS
- Lateral epicondylitis

CONTRAINDICATIONS
- Infection of skin over epicondyle

CPT CODES
20605 Infection of joint
May also charge for office visit

ICD-9 CODES
726.32 Lateral epicondylitis

9. GASTROENTEROLOGY

A. ANOSCOPY

Key Steps

1. Inspect anus.
2. Insert anoscope.
3. Remove obturator.
4. Inspect anorectal mucosa while withdrawing scope.
5. Rotate 90 degrees, reinsert, and inspect.

INSTRUCTIONS
1. The patient is placed in a lateral decubitus position with knees flexed upward toward the chest (Fig. AII-5, *A*).
2. Hold the buttocks apart.
3. Perform a digital exam, allowing for palpation of the anal canal to check for tone, masses, or areas of unusual pain.
4. Lubricate the anoscope with its central guide plug, then slowly insert it past the anal sphincters (Fig. AII-5, *B*).
5. Once the scope is inserted completely, remove the central guide plug for inspection of the distal rectum and the anus (Fig. AII-5, *C* and *D*).
6. Slowly rotate the scope as it is withdrawn to maximize viewing of the mucosa above and below the pectinate line.
7. The operator should be evaluating the mucosa for the presence of mass lesions or hemorrhoids that may be within view (Fig. AII-5, *E*).
8. Masses or polyps that are visible through the scope can be biopsied using a small biopsy forceps.

INDICATIONS
- Suspected anorectal malignancy
- Rectal bleeding
- Hemorrhoid evaluation
- Perianal condyloma
- Anal trauma or foreign body, including sexual assault
- Rectal prolapse
- Anorectal pain

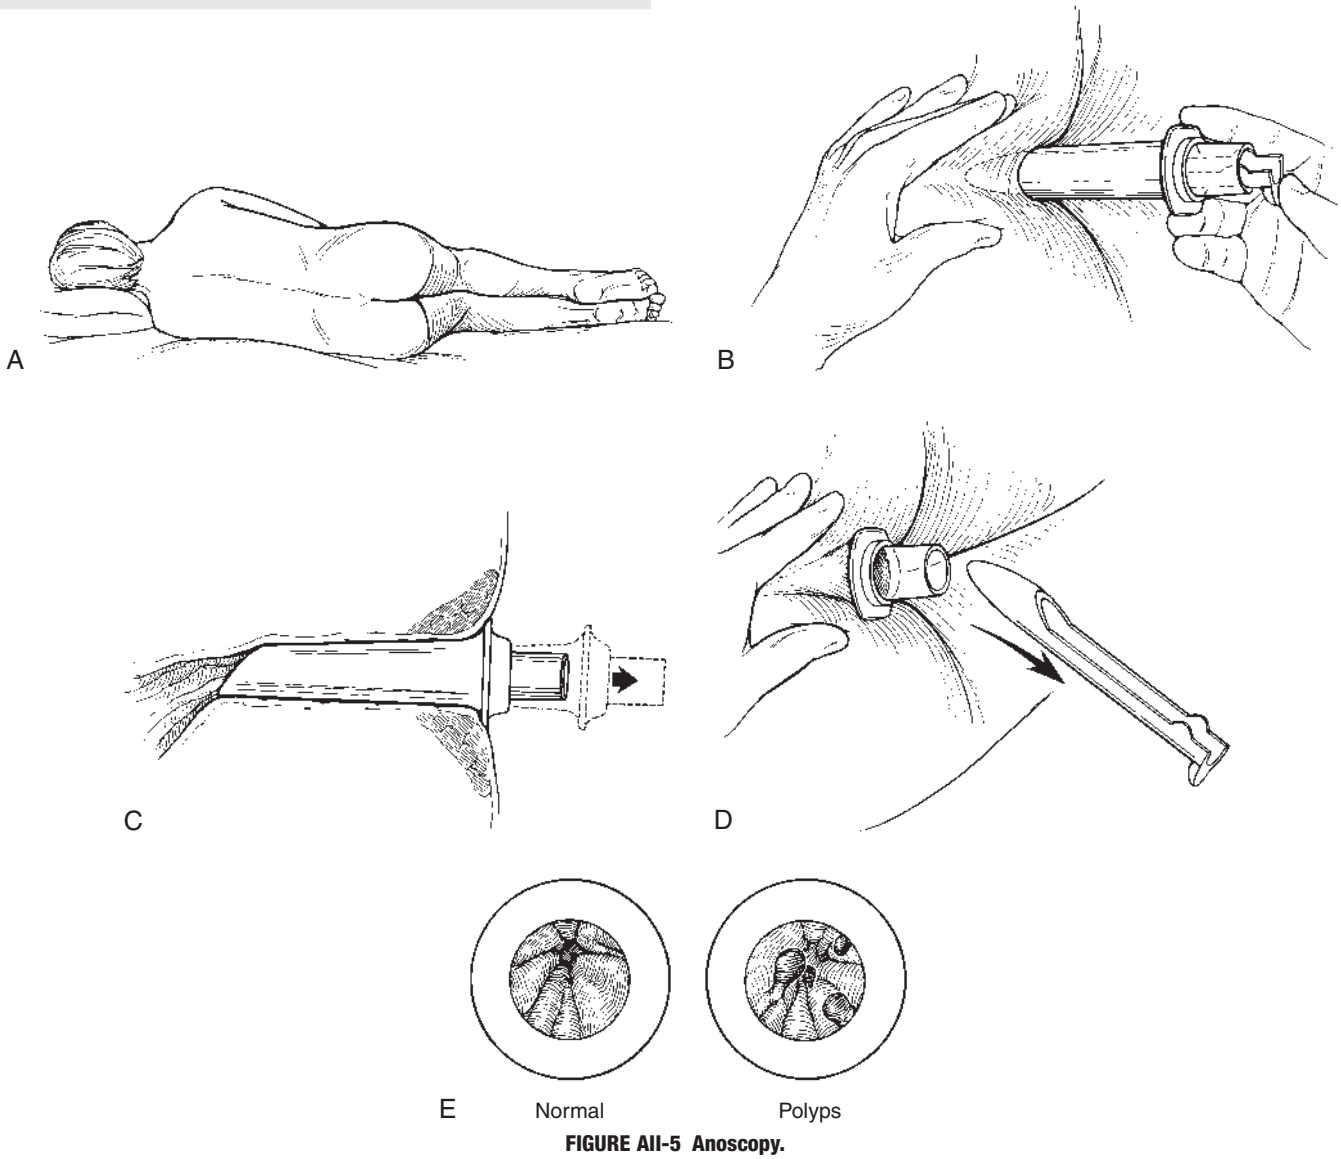

FIGURE AII-5 Anoscopy.

CONTRAINDICATIONS
- Anal canal stenosis or congenital imperforate anus
- Acute cardiorespiratory compromise

CPT CODES
46600 Diagnostic
46606 Biopsy, single or multiple
46900 Destruction of lesion (e.g., condylomata), chemical
46910 Destruction of lesions, electrodessication

ICD-9 CODES
455.0 Internal hemorrhoids
455.2 Internal hemorrhoids, bleeding
455.3 External hemorrhoid
565.0 Anal fissure
569.0 Anal polyp
698.0 Pruritus ani

B. FLEXIBLE SIGMOIDOSCOPY

Key Steps

1. Insert scope.
2. Advance up the sigmoid.
3. Inspect colon while exiting.
4. Examine rectal vault.

INSTRUCTIONS
1. Anoscopy should be performed in all cases in which palpable abnormality is identified.
2. Place the patient in a left lateral position with knees flexed upward toward the chest.
3. Initial digital rectal examination assists in identifying anal fissures, polyps, and lesions, as well as allowing for initial application of lubricant.
4. Perform anoscopy in all cases in which palpable abnormality is identified.
5. Initially advance the scope at an acute angle with the index finger placed behind the advancing tip.
6. As the anal canal is entered, gently rotate the scope in line with the anal canal as the scope advances into the rectum.
7. Once the scope is inserted approximately 15 cm, insert air to see the rectal vault and find the opening to the lower sigmoid.
8. Easily advance the scope up to the most distal turn of the sigmoid.
9. After passing around the first curve, the operator may need to use one of several techniques to encourage the straightening of the colon around the scope.
10. Once the sigmoid has been traversed, enter the descending colon.
11. Here, the colon has a recognizable abundance of rounded haustra.
12. Once maximal insertion is achieved, slowly withdraw the scope and inspect the colon walls, using the 360-degree view technique, gradually rotating the scope.
13. Take care to inspect behind sharp turns in the sigmoid and behind rectal valves.
14. Once the rectum has been inspected, perform retroflexion to view the inside of the anus and lower rectum from above.
15. Insert the scope to approximately 15 cm and fully rotate the dials to a near maximal rotation to allow the scope to be fully retroflexed.
16. When completed, simple rotation of the shaft of the scope on its axis allows for inspection of the rectum and anus.

INDICATIONS
- Rectal bleeding of any type
- Screening for colorectal cancer
- Persons 50 years of age and older, regardless of symptoms
- Unexplained anemia
- Persistent abdominal pain
- Alteration in bowel habits, constipation (particularly unexplained new onset), diarrhea, altered stool diameter
- Unexplained weight loss, fever
- Follow-up of treatment regimens (e.g., for ulcerative colitis, irritable bowel disease)

For the following conditions, colonoscopy may be preferred as first choice to examine the entire colon in patients with higher risk:
- Follow-up for history of polyps or cancer
- Any person with a high-degree risk factor for cancer or other disease in the colon
- Hemoccult-positive stools (positive occult blood)
- Weight loss
- High suspicion of cancer

CPT CODES
45330 Sigmoidoscopy, flexible fiberoptic, diagnostic
45331 Sigmoidoscopy with biopsy
45336 Sigmoidoscopy with ablation of tumor or mucosal lesion

ICD-9 CODES
558.9 Colitis, nonspecific
564.0 Unspecified constipation
564.1 Irritable colon
569.3 Anal hemorrhage
578.1 Melena
789.0 Abdominal pain
V16.0 Family history of colon cancer

C. INTERNAL HEMORRHOID BANDING

Key Steps

1. Prepare banding tool.
2. Perform anorectal inspection.
3. Grasp hemorrhoid with forceps.
4. Release band at base of hemorrhoid.

INSTRUCTIONS
1. Prior to initiation of the banding procedure, prepare the instruments and load the rubber band on the banding forceps.
2. First, place the conical attachment on the banding forceps, slide the rubber band down, and gradually expand it until it fits around the ring portion of the banding forceps.
3. Then adjust the rubber band to the distal edge of the banding forceps so that only a small closure of the forceps will allow the release of the band.
4. Place the patient in a decubitus position, with knees flexed upward toward the chest.
5. Locate the anoscope and insert it into the rectal vault.
6. Prior to banding, ascertain that the hemorrhoid is anesthetized and truly is an internal hemorrhoid.
7. In most instances, identify internal hemorrhoids by their origin proximal to the dentate (or pectinate) line and the fact that they are not sensitive to simple grasping.
8. Insert the grasping forceps through the banding forceps and use it to grasp the body of the hemorrhoid to band.
9. Grasp the hemorrhoid and advance the banding forceps forward.
10. While squeezing the handle, release the rubber band around the proximal end of the hemorrhoid tissue.
11. Painless necrosis of the hemorrhoid will occur within 2 to 3 days, allowing the sloughed tissue to pass in the stool.

INDICATIONS
- Symptomatic internal hemorrhoids not responsive to conservative therapy

CONTRAINDICATIONS
- Coagulopathy
- Anal infection
- Anal fissure
- Anal tumor
- Pregnancy

CPT CODES
46221 Hemorrhoidectomy by simple ligature, banding

ICD-9 CODES
455.0 Internal hemorrhoids

D. EXTERNAL HEMORRHOID EXCISION

Key Steps

1. Cleanse perianal area.
2. Inject anesthesia.
3. Isolate hemorrhoidal tissue.
4. Excise hemorrhoid.

INSTRUCTIONS

1. The ideal position for anal surgery is to position the patient on the Ritter table with hip and knees flexed in the "bottoms up" position (Fig. AII-6, *A* and *B*).
2. An acceptable alternative is to place the patient in a left lateral position with knees flexed upward toward the chest and with the buttocks held open by an assistant.
3. Clean the anal area with Betadine solution. (First check for iodine allergy.)
4. With an acutely thrombosed hemorrhoid, marked tenderness to palpation is common (Fig. AII-6, *C*).
5. In this case of a chronic recurrent hemorrhoid, the hemorrhoid is nontender; however, the excision technique is the same.
6. Local anesthetic consisting of a combination of lidocaine and bupivacaine provides longer anesthesia and is used to provide a local block (Fig. AII-6, *D*).
7. Prior application of topical 20% benzocaine solution can diminish injection site pain.
8. Inject the hemorrhoid around all aspects of its base to ensure complete anesthesia.
9. Injecting the hemorrhoid itself is not necessary if the base is anesthetized.
10. A single, deep injection is also necessary for acute hemorrhoid to allow for extraction of clot within the lesion.
11. Once anesthesia is complete and has been allowed to take effect, test the hemorrhoid for sensation.
12. Once the hemorrhoid is anesthetized, clamp and stabilize it with hemostats and excise the hemorrhoid across the base of the lesion in an elliptical fashion.

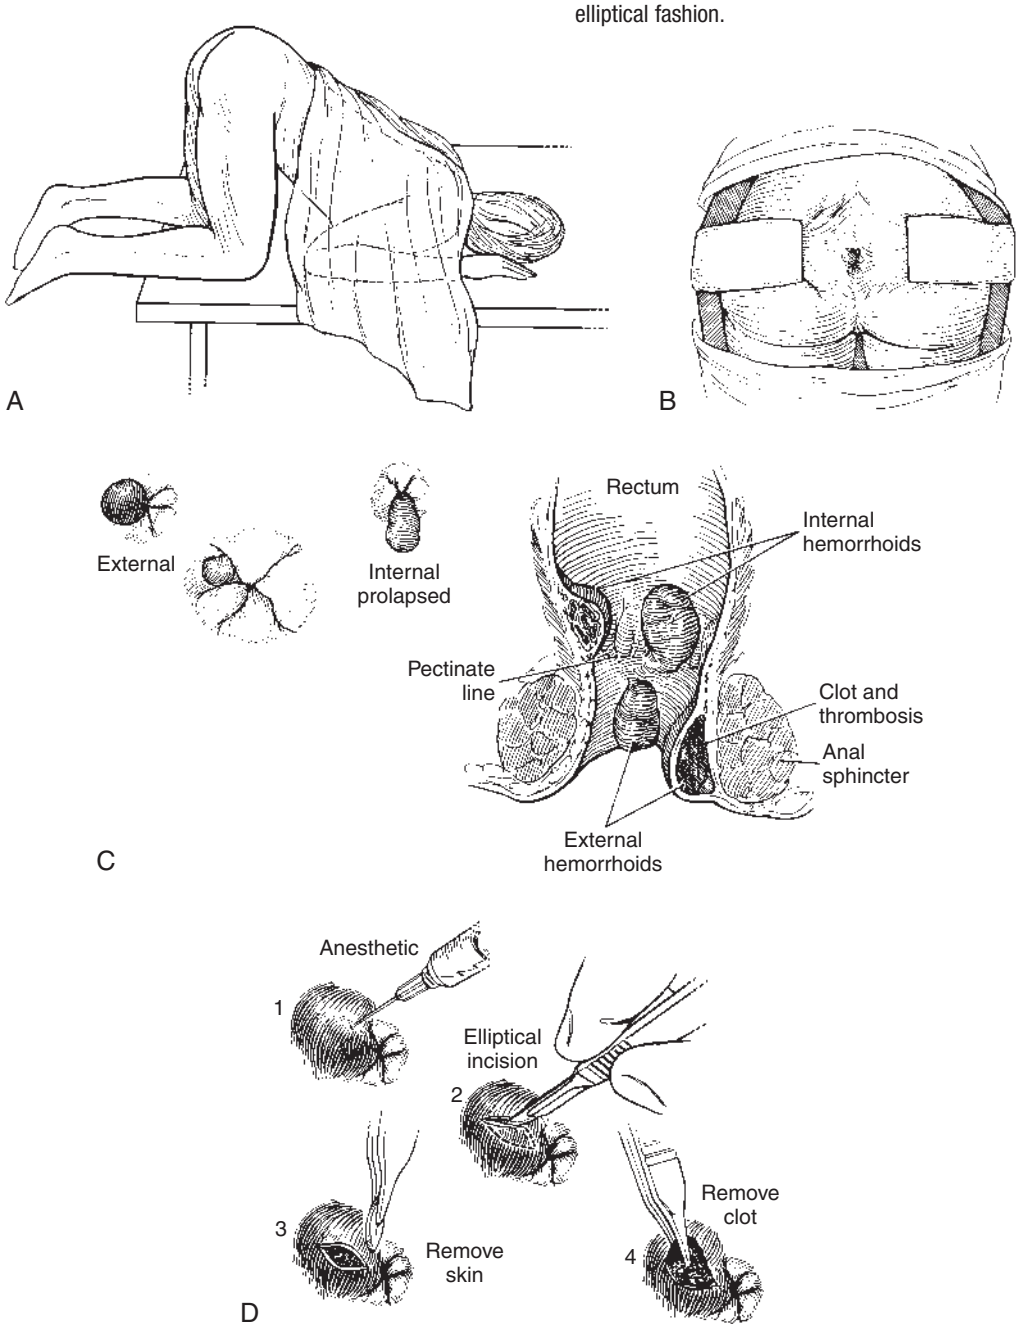

FIGURE AII-6 External hemorrhoid excision.

13. If there are any visible clots, extract them from the hemorrhoid using the hemostats.
14. Usually, there is minimal bleeding in the wound, which can be left open and allowed to drain while it is healing.
15. Persistent bleeding may require application of Surgicel or Monsel's solution.
16. Proper cleansing of the area postoperatively is important to ensure minimal likelihood of infection.

INDICATIONS
- Pain, itching, and burning of thrombosed hemorrhoids
- Poor hygiene and/or difficult stooling secondary to pain
- Failure to respond to local therapy such as sitz baths and topicals

CONTRAINDICATIONS
- Poorly characterized bleeding disorder

CPT CODES
46083 Incision and drainage of thrombosed hemorrhoids

ICD-9 CODES
455.3 External hemorrhoids
455.2.1 External hemorrhoids thrombosed

E. NASOGASTRIC INTUBATION

Key Steps

1. Determine widest nares for insertion.
2. Apply topical anesthetic in nares and throat.
3. Insert tube.
4. Check placement tube.

INSTRUCTIONS
1. Place the patient in a sitting position with the head angled forward in a sniffing posture.
2. Apply topical anesthetic either by spray or gel into the nares selected for insertion.
3. Anesthetizing the back of the throat can also reduce the risk of vomiting during nasogastric (NG) tube insertion.
4. Insert the NG tube along the floor of the nose gently and down the nasopharynx.
5. As the tube approaches the larynx and upper esophagus, the patient should tilt his or her head slightly downward to encourage the tube to pass posteriorly into the esophagus.
6. Advance the tube to the stomach.
7. Test and confirm the tube position by aspiration of gastric contents, which should have a pH of less than 6.
8. If the patient is unconscious or sedated, perform a confirmatory x-ray.
9. If feeding is planned through the tube, confirm its position by x-ray in all patients.

INDICATIONS
- Relief of upper gastrointestinal obstruction
- Drainage of gastric contents, bowel rest
- Need for tube-delivered nutrition, dye, or medications

CONTRAINDICATIONS
- Facial fractures involving the nose, maxilla, basal bones of the skull, or suspected cervical spine fracture
- Unprotected airway in nonresponsive patient
- Penetrating wound of the neck or chest
- Nasal obstruction
- Esophageal obstruction or anomaly
- Sepsis or bacteremia not coming from the joint
- Placement of percutaneous endoscopic gastrostomy tube would be more appropriate

CPT CODES
43752 Nasogastric or orogastric tube placement necessitating physician's skill
89130 Gastric intubation and aspiration, diagnostic
91105 Gastric intubation and aspiration, therapeutic

ICD-9 CODES
536.2 Vomiting, persistent
537.0 Gastric outlet obstruction
560.1 Ileus, paralytic
561.81 Small bowel obstruction, adhesions
578.0 Hematemesis
578.1 Hematochezia
578.9 GI bleeding, unspecified
787.01 Vomiting, NOS with nausea
977.9 Poisoning, unspecified

10. GYNECOLOGY

A. PAP SMEAR

Key Steps

1. Inspect external genitalia.
2. Insert speculum.
3. Obtain spatula and brush samples.
4. Liquid-based Pap smear sampling.

INSTRUCTIONS
1. Inspect the external genitalia for lesions, then carefully insert the speculum.
2. Advising the patient to relax the perineal musculature can make insertion much less uncomfortable.
3. Clearly visualize the cervix.
4. Perform the Pap smear in several ways.
5. Using a Pap spatula, place the tip of the spatula within the os, and rotate the spatula several times to collect cells on one face.
6. When spreading the spatula over a slide, one must take care that the side that is laden with cells is spread over the glass surface.
7. The cervical brush obtains excellent endocervical samples. It can be used alone, but use it most often in conjunction with the spatula.
8. Commonly use the broom-shaped Pap device with the wet prep and human papillomavirus (HPV) sampling.
9. Place the point of the broom within the os and rotate the brush five times to obtain the sample.
10. Remove the tip of the brush and place it within the wet prep container.
11. Send this sample for both cytology and HPV typing as indicated.

INDICATIONS
- Women of reproductive age who are sexually active
- Women who are HIV positive
- Immunocompromised women
- During prenatal care workup

CONTRAINDICATIONS
- Active vaginal, cervical, or uterine infection

RELATIVE CONTRAINDICATION
- Blood contamination, especially if heavy

CPT CODES
87621 HPV sampling—Wet prep Pap
99201-99215 Pap smear and endocervical culture

ICD-9 CODES
795.00 Abnormal Pap
V25.9 Contraceptive management
V70.0 Well adult exam

V72.31 Gynecologic screening exam
V72.32 Follow up abnormal Pap
V13.29 Personal history other genital system and obstetric disorders

B. BARTHOLIN'S MARSUPIALIZATION

Key Steps

1. Determine incision site and anesthetize.
2. Make incision and remove cyst roof.
3. Identify layers for closure.
4. Suture with circumferential stitches.
5. Complete marsupialization.

INSTRUCTIONS

1. The patient is placed in the lithotomy position, and the perineum is washed with antiseptic solution.
2. Palpate the cyst manually to clearly identify its size and location.
3. Outline the incision with a surgical marker at the junction of the vaginal sidewall and labia minora.
4. The incision should be a 2- to 3-cm ellipse whose long axis follows the internal axis of the vaginal side wall, not involving the external labial skin.
5. Use a 15-blade scalpel to create the ellipse to be excised.
6. Enter the vaginal mucosa followed by careful incision through the fascia overlying the cyst.
7. Several layers of fascia and vaginal wall smooth muscles are divided in this process.
8. Open these layers sharply until the cyst wall is entered and drainage occurs.
9. Once the cyst is entered and drained, excise fully the ellipse of tissue, effectively removing the roof of the cyst adjacent to the vaginal sidewall.
10. What remains is the smooth cyst cavity with its distinct edge that must be clearly identified before beginning closure.
11. Use a 3-0 Dexon or Vicryl suture to marsupialize the cyst.
12. Place the initial stitch by passing the needle through the mucosa and then passing through the cyst wall from the submucosal side to open the remaining portion of the cyst.
13. Run the suture continuously around the margin of the incision in small 2- to 3-mm bites.
14. Each stitch must take the vaginal mucosa and cyst wall together.
15. Once the last stitch is placed, overlapping the initial anchoring stitch, tie the suture securely.
16. At the completion of the procedure, one can see that the cyst wall is clearly opened and retracted by the circumferential stitches.
17. Immediately postop, the appearance is that of a small cleft on the side where the surgery was performed.
18. After several days, the repair is barely noticeable as the vaginal wall further contracts.

INDICATIONS

- Failed Word catheter treatment in the acute setting
- Recurrent infections or reaccumulation of Bartholin's gland cyst fluid

CONTRAINDICATIONS

- Cysts that could be adequately treated with a Word catheter
- Coagulation defect (either medication related, congenital, or acquired) that is uncorrected
- Patient who is unable to comply with wound care

CPT CODES

56440 Bartholin's gland cyst marsupialization

ICD-9 CODES

616.2 Bartholin's cyst
616.3 Bartholin's abscess

C. BARTHOLIN'S CYST WORD CATHETER PLACEMENT

Key Steps

1. Inject local anesthesia.
2. Make incision into abscess.
3. Place catheter.
4. Inflate balloon.

INSTRUCTIONS

1. Place the patient in the lithotomy position and wash the perineum with antiseptic solution.
2. Manually palpate the Bartholin's abscess to clearly identify its size and location (Fig. AII-7, *A*).
3. Identify the incision site at the junction of the vaginal mucosa and the labia minora.
4. Inject local anesthesia of 1% to 2% lidocaine at the incision site.
5. Anesthetize both the skin and deeper fascia overlying the abscess.
6. Test the Word catheter to ensure that it will function properly.
7. Inject 2 to 3 ml of saline into the catheter port, fill, and inspect the balloon.
8. Withdraw the fluid from the catheter prior to insertion.
9. Leave the needle in the catheter port to use promptly after inserting the catheter into the abscess.
10. Use a 15-blade scalpel to incise the wall overlying the abscess; spontaneous drainage of the abscess will occur (Fig. AII-7, *B*).
11. After expressing and draining the entire abscess, insert the Word catheter through the opening (Fig. AII-7, *C*).
12. Take care to insert the tip of the catheter fully into the Bartholin's cyst cavity, not just within the fascia space overlying the cyst.
13. Once the tip is in the infected cyst cavity, inflate the balloon with 3 ml of saline and withdraw the needle from the injection port (Fig. AII-7, *D*).
14. Apply pressure to the syringe to avoid loss of fluid from the catheter.
15. Once the insertion is complete, inspect the area for bleeding.
16. Provide the patient with a perineal pad to collect any further drainage that may occur after the procedure.
17. Recommend postoperative follow-up in 2 to 3 days to ensure that the catheter placement is appropriate and that the abscess continues to drain.
18. Leave the catheter in place for 4 to 6 weeks to induce epithelialization of the cyst and drainage track, preventing further abscess formation.

INDICATIONS

- Acute infections
- Pain from cyst enlargement
- Obstructive Bartholin's gland cyst affecting the patient's sexual activity or obstructing the vaginal orifice

CONTRAINDICATIONS

- Cysts that should be treated by marsupialization
- Coagulation defect (either medication related, congenital, or acquired) that is uncorrected

CPT CODES

56420 I&D of Bartholin's gland cyst

ICD-9 CODES

616.2 Bartholin's cyst
616.3 Bartholin's abscess

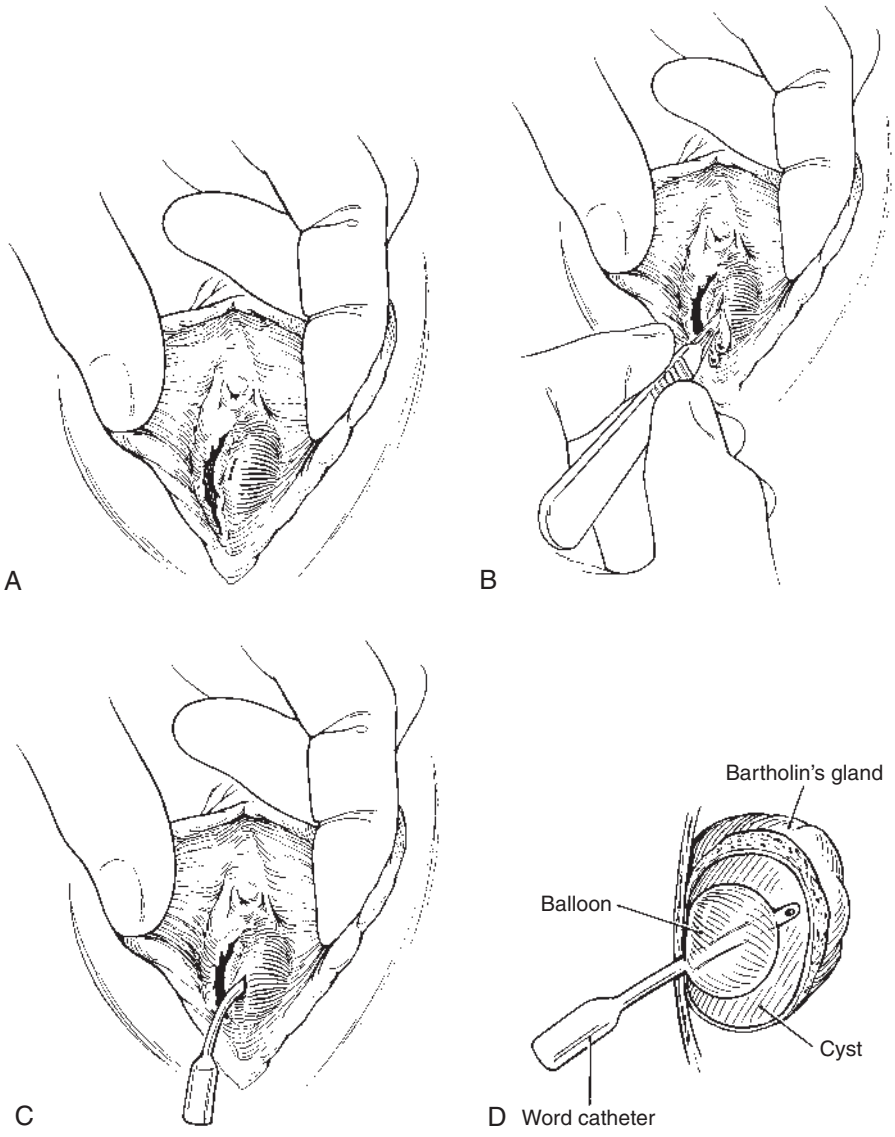

FIGURE AII-7 Bartholin's cyst Word catheter placement.

D. VULVAR BIOPSY

Key Steps

1. Evaluate visible lesions.
2. Cleanse skin with antiseptic.
3. Infiltrate with local anesthesia.
4. Biopsy selected area.
5. Perform closure and hemostasis.

INSTRUCTIONS

1. Clean the vulva with Betadine solution. (First check for iodine allergy.)
2. Inject local anesthetic underneath the biopsy site, allowing it to elevate and provide an ideal platform for a punch biopsy.
3. Select a suitably sized punch biopsy to yield a sample through the dermal layer.
4. Excise the core of the punch biopsy using iris scissors and small Adson's forceps.
5. If bleeding is minimal, simple application of Monsel's solution provides adequate hemostasis.
6. If bleeding persists, use a single suture of 5-0 chromic or other absorbable suture.
7. Submit all samples for pathology.

INDICATIONS

- Any unidentifiable or concerning lesion
- Lesion that does not respond to conventional therapy
- Pigmented lesions
- Atypical nevi
- Vulvar ulceration of uncertain etiology
- Leukoplakia
- Acetowhite epithelium
- Vulvodynia with acetowhite epithelium (tissue that turns white after the application of vinegar)
- Presumed condylomata that are not responding to conventional therapy (following two treatment attempts of any kind)
- Postmenopausal woman with atrophic vaginitis that does not respond to estrogen therapy and no other cause is evident
- Any skin abnormality requiring definitive diagnosis

CONTRAINDICATIONS

- Poorly controlled infection over biopsy site (treat then biopsy)
- Caution with large excisional biopsies with anticoagulation

CPT CODES

56605 Biopsy of vulva
56606 Biopsy of vulva more than one lesion
56820 Colposcopy of vulva
56501 Lesion destruction of vulva

ICD-9 CODES
624.9 Unspecified noninflammatory disorder of vulva and perineum
078.11 Condyloma acuminatum
221.2 Benign vulvar neoplasm
624.8 Vulvar dysplasia

11. INPATIENT MEDICINE

A. LUMBAR PUNCTURE

Key Steps

1. Identify landmarks.
2. Inject local anesthetic at insertion site.
3. Insert spinal needle into cerebrospinal fluid space.
4. Collect cerebrospinal fluid.
5. Remove spinal needle.

INSTRUCTIONS
1. Place the patient in the flexed lateral decubitus position (Fig. AII-8, *A*). Upright position is also acceptable (Fig. AII-8, *B*).
2. Cleanse the skin with antiseptic solution.
3. The iliac crest serves as the landmark that marks the interspace between the third and fourth lumbar vertebrae (Fig. AII-8, *C*).
4. Place a fenestrated drape over this space after it is marked.
5. Anesthetize the skin and deep connective tissue with 1% lidocaine.
6. Insert a 21-gauge spinal needle through the interosseous ligament into the intervertebral space.
7. Advance the needle toward the umbilicus between the L3 and L4 vertebrae, checking periodically if the physician senses that the needle may have entered the dural space (Fig. AII-8, *D*).
8. Usually a "pop" is felt on entering the spinal canal.
9. Once the canal is entered, remove the obturator and allow the spinal fluid to flow out into the collection tube.
10. Normally, collect three or four tubes with 1 to 3 ml of fluid each and label them sequentially for cerebrospinal fluid (CSF) studies.
11. After the collection of fluid is complete, replace the obturator and remove the needle.
12. Place an adhesive bandage over the puncture site.

INDICATIONS
- Suspected meningitis or cerebral infection
- Evaluation of CSF or pressures for diagnostic purposes (Guillain-Barré syndrome, lupus, multiple sclerosis, pseudotumor cerebri, suspected central nervous system malignancy)
- Intrathecal or spinal anesthetic
- Imaging procedures where dye infusion into the CSF is necessary

CONTRAINDICATIONS
- Local infection at the site of lumbar puncture
- Coagulation defect (either medication related, congenital, or acquired), relative
- Suspected increased intracranial pressure
- Suspected brainstem herniation

CPT CODES
62270 Spinal puncture, diagnostic
62272 Spinal puncture, therapeutic for drainage of CSF

ICD-9 CODES
322.9 Suspected meningitis
340.00 Multiple sclerosis
348.2 Pseudotumor cerebri
357.0 Guillain-Barré syndrome
710.0 Systemic lupus erythematosus
852.00 Subarachnoid hemorrhage

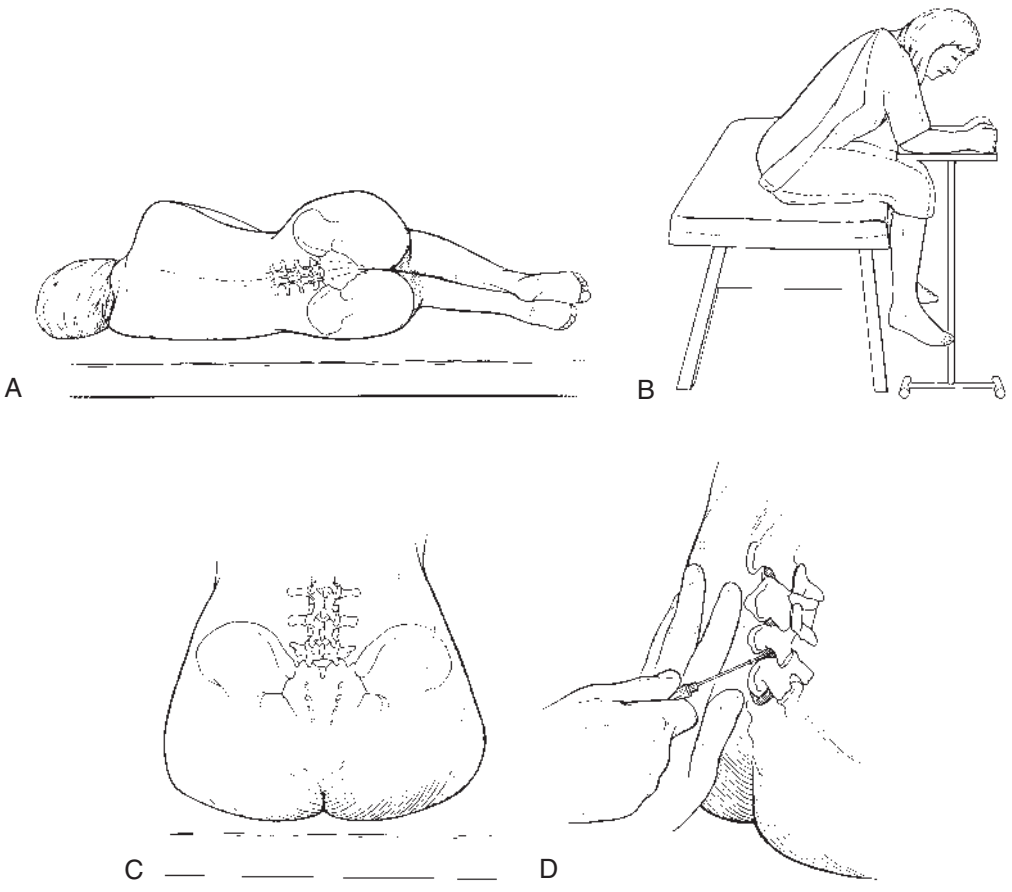

FIGURE AII-8 Lumbar puncture.

B. SUBCLAVIAN LINES

Key Steps

1. Identify landmarks.
2. Inject local anesthesia at insertion site.
3. Insert trocar and place wire.
4. Exchange trocar for dilator and catheter over wire.
5. Suture catheter to skin.

INSTRUCTIONS

1. Place the patient in Trendelenburg's position at about 15 degrees and clean, shave, and drape the skin over the midclavicular region.
2. Identify the key landmarks of the midclavicle and the suprasternal notch by palpation.
3. Inject local anesthetic along the planned trajectory of the catheter insertion (Fig. All-9, *A*), notably anesthetizing the periosteum of the clavicle to avoid pain as the insertion needle passes underneath the clavicle.
4. Insert the introducer trocar at the midclavicular line and pass it under the clavicle, keeping its tip aiming toward the sternal notch (Fig. All-9, *B*).
5. Retract the syringe plunger to create negative pressure so that when the subclavian vein is entered, a flash is seen in the syringe.
6. Once this occurs, insert the wire through the trocar (Fig. All-9, *C*), taking care to use the thumb to prevent any air intake into the trocar during transfers.
7. At no time should the operator let go of the wire while it is in the patient (Fig. All-9, *D*).
8. Insert the wire at least 20 cm.
9. Remove the insertion trocar and incise the skin with an 11 blade to allow the dilator to pass easily (Fig. All-9, *E*).
10. Pass the catheter and dilator over the wire (Fig. All-9, *F*).

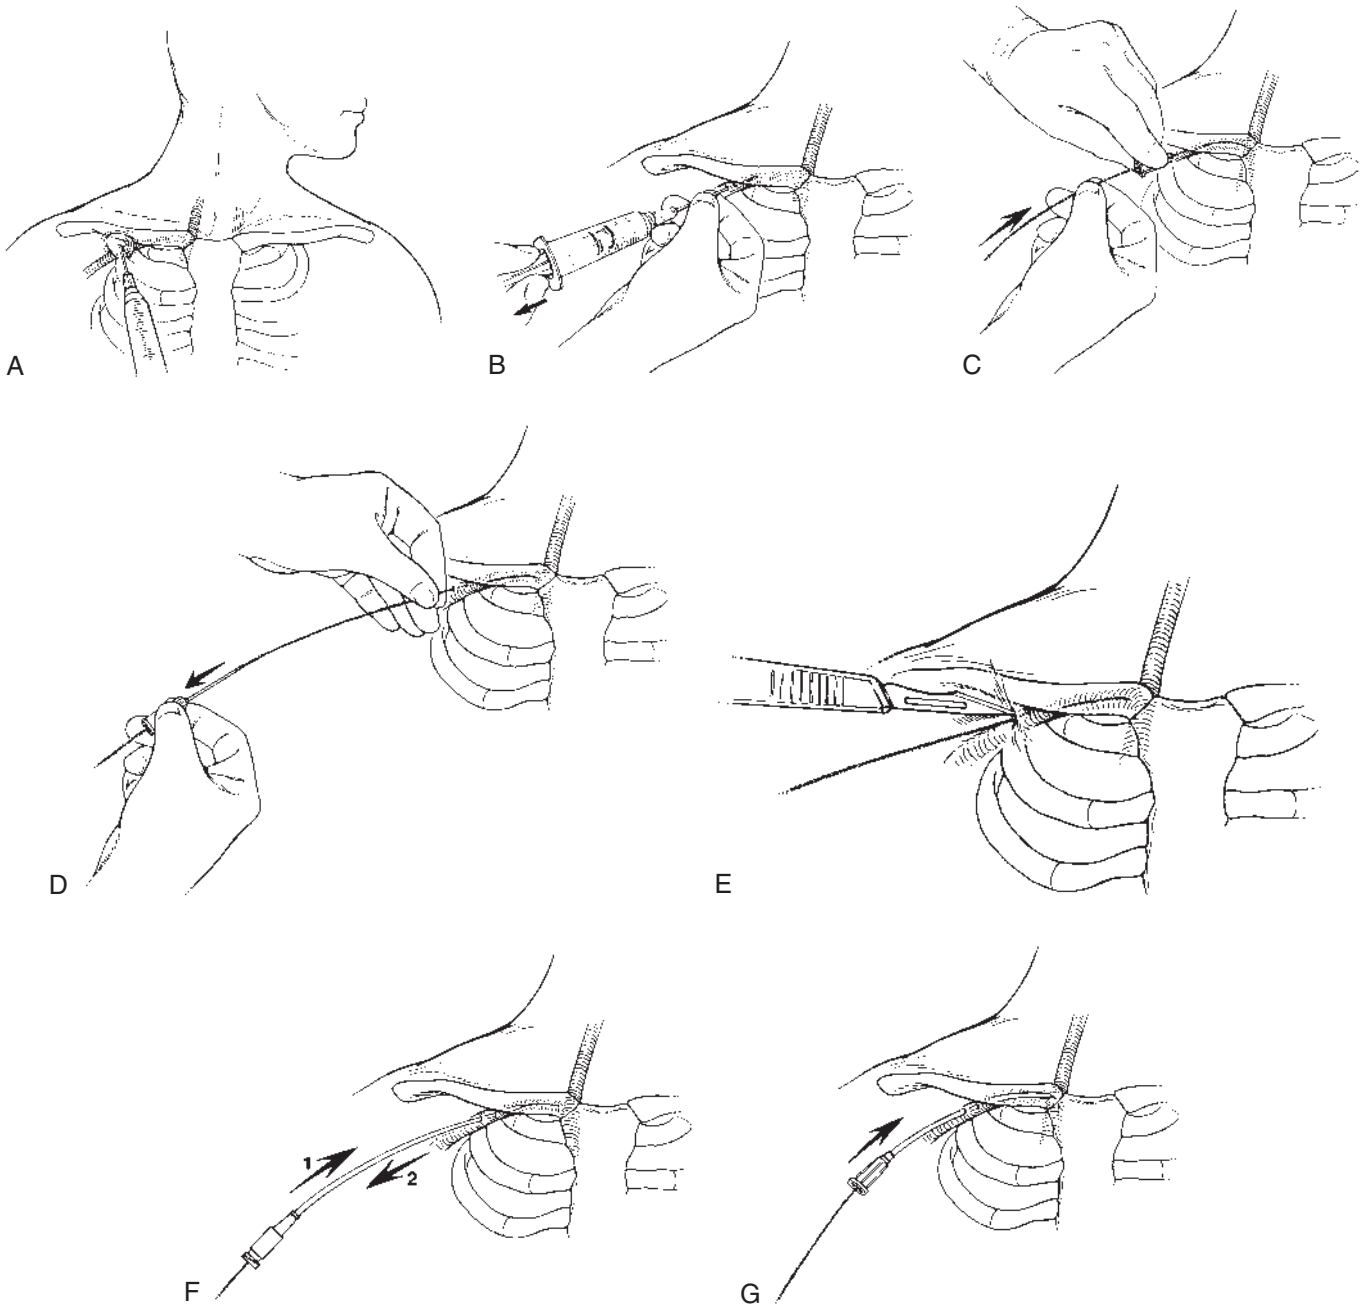

FIGURE AII-9 Subclavian line.

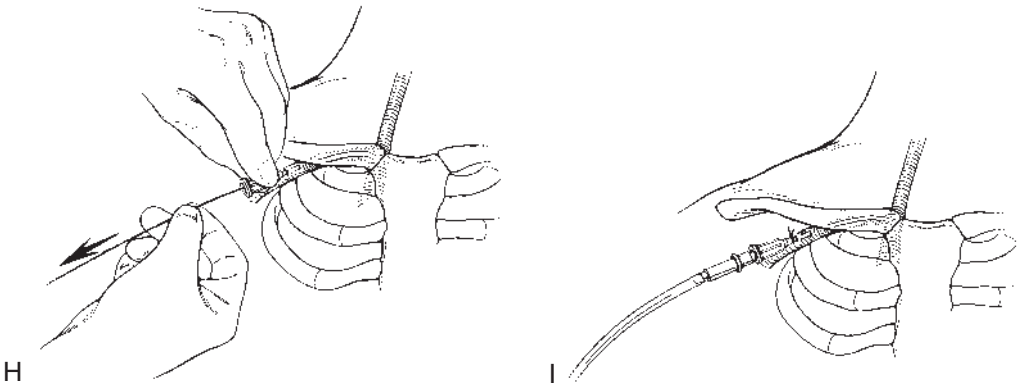

FIGURE AII-9 (Continued)

11. As soon as the wire is visible at the distal end of the catheter, release one hand from the wire proximally and grasp the wire at the distal end.
12. Fully insert the catheter before withdrawing the wire (Fig. AII-9, *G*).
13. Then remove the dilator and test the catheter before securing it to the patient's skin with suture (Fig. AII-9, *H*).
14. Proper venous flow through the catheter suggests proper placement of the catheter.
15. Connect the catheter hub to an IV set (Fig. AII-9, *I*) and obtain a chest x-ray to confirm placement and ensure that a pneumothorax has not occurred due to catheter insertion.

INDICATIONS
- Central venous access for fluid resuscitation, hyperalimentation, or delivery of medications in intensive-care situations
- Delivery of medications that may cause sclerosis of smaller veins or necrosis of tissue if leaked from a peripheral vein
- Vascular access for plasmapheresis, dialysis, pacemakers, or Swan-Ganz catheter placement
- Vascular access for pulmonary or cardiac catheterization

CONTRAINDICATIONS
- Chest injury where a pneumothorax on the side of the line placement would compromise patient's survival
- Coagulation defect (either medication related, congenital, or acquired)
- Chest wall deformity or defect, congenital or acquired
- Infection or burn of the chest wall where the line would be placed

CPT CODES
36010 Introduction of catheter, superior or inferior vena cava
36011 Selective catheter placement, venous system, first-order branch, e.g., jugular vein

ICD-9 CODES
276.5 Dehydration
785.5 Shock, unspecified
785.59 Shock (hypovolemic, septic)

C. THORACENTESIS

Key Steps

1. Determine level of effusion.
2. Inject local anesthesia at insertion site.
3. Insert trocar and catheter.
4. Remove catheter.

INSTRUCTIONS
1. Prior to performing a thoracentesis, the operator must determine the level of pleural fluid with the patient sitting in the upright position (Fig. AII-10, *A*).
2. This can be done with percussion of the chest, egophony, or imaging studies.
3. Select an entry site just superior to a rib, along the posterior midclavicular line.
4. Clean the skin with an antiseptic solution and place a sterile drape over the area.
5. Draw up local anesthetic into a syringe using a 23-gauge, 1.5-inch needle to inject the anesthetic.
6. After creating a superficial wheal, pass the needle deep into the intercostal muscle, where 1 ml is injected.
7. Advance the needle 1 cm at a time, injecting 1 ml of anesthetic each time to anesthetize the deep layers superficial to the pleura.
8. Apply negative pressure to the syringe while advancing it.
9. A palpable "pop" can be felt when penetrating the tough, fibrous pleura.
10. Inject 2 ml of anesthetic into the pleural space and then withdraw the needle only slightly to infuse 1 ml more of anesthetic at the pleura.
11. This technique provides superb anesthesia.
12. Carefully insert the trocar just above the rib where the anesthesia has been placed.
13. Apply negative pressure to the syringe so that it is obvious when the pleural space is entered (Fig. AII-10, *B*).
14. Advance the catheter and then withdraw the trocar, leaving the catheter in the pleural space to collect fluid.
15. The catheter is never withdrawn through the trocar as long as either device is in the patient.
16. Using a large syringe, withdraw 30 to 60 ml of fluid to send for pathologic studies.
17. If a large effusion is present, then perform a therapeutic thoracentesis during which as much as several liters of fluid can be removed in one setting (Fig. AII-10, *C*).
18. After removing the desired amount of fluid, carefully and quickly withdraw the catheter to avoid an air leak into the chest cavity.
19. Cover the wound with a simple bandage and obtain a postthoracentesis x-ray.

INDICATIONS
- Diagnostic collection of pleural fluid
- Therapeutic extraction of pleural fluid affecting respiratory status
- Relief of spontaneous pneumothorax, though larger-caliber chest tubes are optimal

CONTRAINDICATIONS
- Coagulation defect (either medication related, congenital, or acquired), relative
- Suspicion that the lung is adherent to pleura
- Loculated fluid collection in the chest, in which case ultrasound guidance is recommended

CPT CODES
32000 Thoracentesis, puncture of pleural cavity for aspiration, initial or subsequent

ICD-9 CODES
511.9 Pleural effusion
511.1 Bacterial effusion
512.8 Pneumothorax

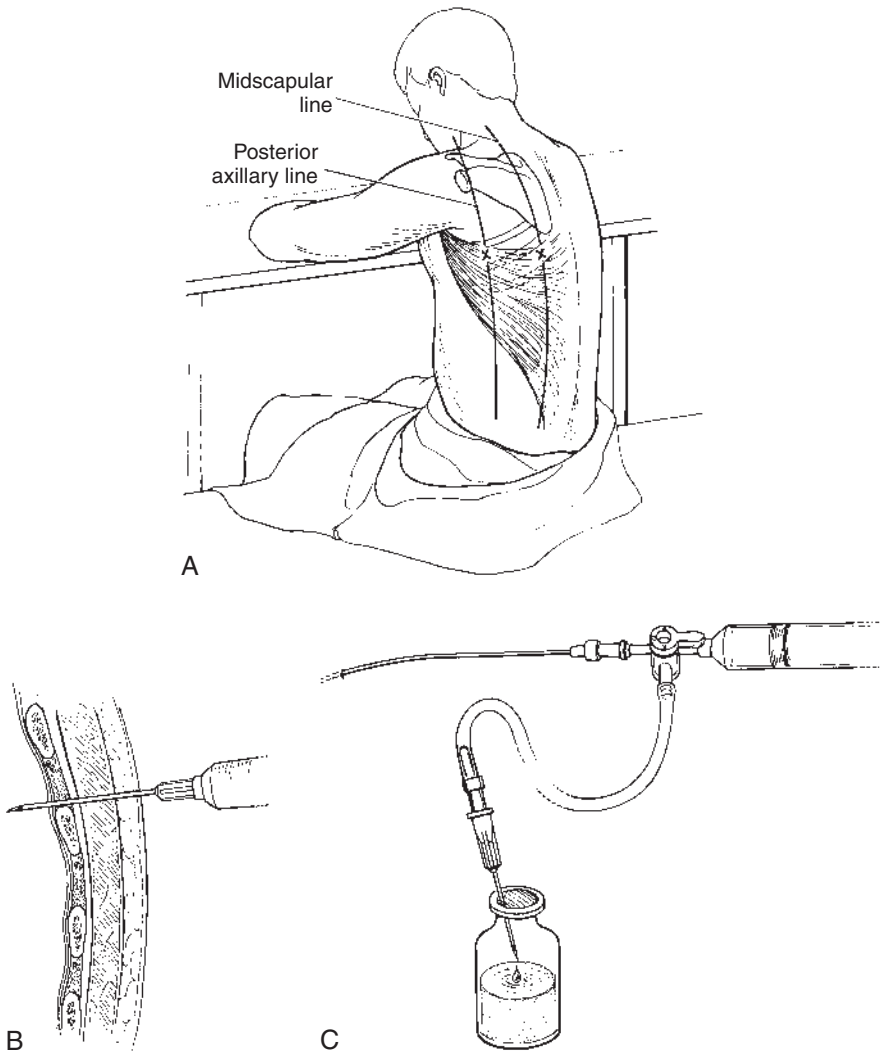

FIGURE AII-10 Thoracentesis.

D. ABDOMINAL PARACENTESIS

Key Steps

1. Cleanse skin site.
2. Inject local anesthesia at entry point.
3. Insert IV or fenestrated catheter.
4. Remove device.

INSTRUCTIONS

1. Place the patient in a supine position rolled toward the left and cleanse the site with antiseptic solution.
2. Select the insertion site on or near the midclavicular line (Fig. AII-11, *A*).
3. Cover the area with a sterile protective drape.
4. Place a local anesthetic block.
5. First, place a wheal in the skin, then advance the needle into the subcutaneous layer and inject 1 ml of solution (Fig. AII-11, *B*).
6. Advance the needle into the muscle and inject the anesthetic into that layer as well.
7. Finally, as the needle is slowly advanced through the peritoneum, maintain suction on the syringe until entering the abdominal cavity (Fig. AII-11, *C*).
8. Once ascitic fluid is obtained, withdraw the needle slowly as 1 to 2 ml of lidocaine is injected to numb the peritoneal layer (Fig. AII-11, *D*).
9. There are two options for draining fluid.
10. For diagnostic paracentesis when removing small volumes, use an IV catheter to obtain a fluid sample.
11. Advance the catheter while applying suction by a syringe until the cavity is entered and fluid enters the syringe.
12. For therapeutic paracentesis, pass a larger catheter through a trocar into the peritoneal cavity.
13. Advance the trocar through the anesthetic area into the peritoneal cavity.
14. Then advance the catheter into the peritoneal cavity through the trocar.
15. Several liters of fluid can be drained from the abdomen using vacuum bottles attached to the catheter system.
16. Attach a stopcock system to the catheter.
17. This allows for control of the suction as desired during collection of the fluid.
18. The fluid will flow until the majority of the fluid is removed.
19. At the conclusion of the procedure, remove the needle and catheter.
20. Apply a dressing over the wound in case there is any further fluid leak.

INDICATIONS

- Intraabdominal ascites
- Suspected bacterial peritonitis
- Need for tube delivered nutrition, dye, or medications

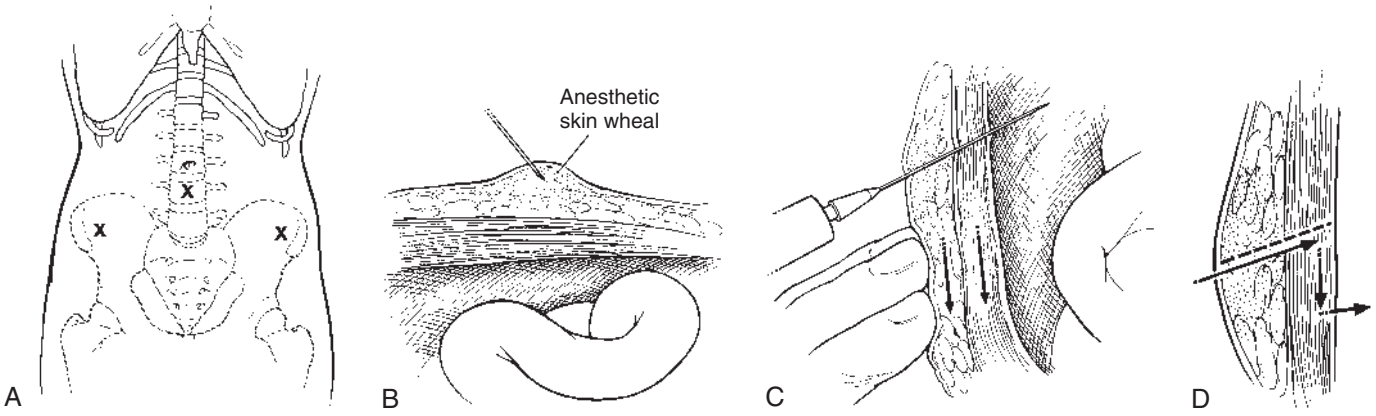

FIGURE AII-11 Abdominal paracentesis.

CONTRAINDICATIONS
- Coagulation defect (either medication related, congenital, or acquired)
- Second-trimester or third-trimester pregnancy
- Previous abdominal surgeries (multiple, in which adhesions are more likely)
- Local infection at the site of paracentesis
- Acute abdomen, acute distension (not ascites), or bowel obstruction

CPT CODES
49080 Abdominal paracentesis or peritoneal lavage, initial
49081 Abdominal paracentesis or peritoneal lavage, subsequent

ICD-9 CODES
789.5 Ascites
197.6 Ascites, malignant
567.2 Subacute bacterial peritonitis
014.0 Ascites, tuberculous

12. OBSTETRICS

A. VAGINAL DELIVERY

Key Steps

1. Complete the second stage.
2. Controlled delivery of the head.
3. Delivery of the shoulders.
4. Delivery of the placenta.

INSTRUCTIONS

First Stage of Delivery

1. During the ending of the first stage of delivery, the fetal head engages the maternal pelvis and rotates from a transverse lie to a coronal lie.
2. Normally, the head aligns with the fetal occiput anterior, though occiput posterior may occur approximately 20% of the time.
3. Once the rotation is complete, it allows for easier descent through the pelvic floor through the vagina.
4. Once the patient is fully dilated to 10 cm, she often has a strong urge to push with contractions.
5. Ideally, three or four pushes are done with each contraction, each push lasting 8 to 10 seconds.
6. The propulsive effort of both the uterine contraction and the Valsalva pressure supplied by the abdominal muscles and diaphragm moves the infant's head farther down the vaginal canal.

Second Stage of Delivery

1. The normal second stage of labor is approximately 1 hour for most multiparous patients and up to 2 hours for primiparous patients.
2. As the fetus moves farther down to +3 to +4 station, the infant's head becomes visible as the labia separate with each push (Fig. AII-12, *A*).
3. If tolerated by the infant, allowing the perineum to stretch reduces the degree of tearing as the head is delivered.
4. When the head is crowning, slight counterpressure to the head applied during the delivery process can prevent a rapid expulsion of the head as it passes through the final resistance of the vulva (Fig. AII-12, *B*).
5. Once the head is delivered, the operator tracks a finger along the neck to check for a nuchal cord (Fig. AII-12, *C*). If a cord is present, reduce it

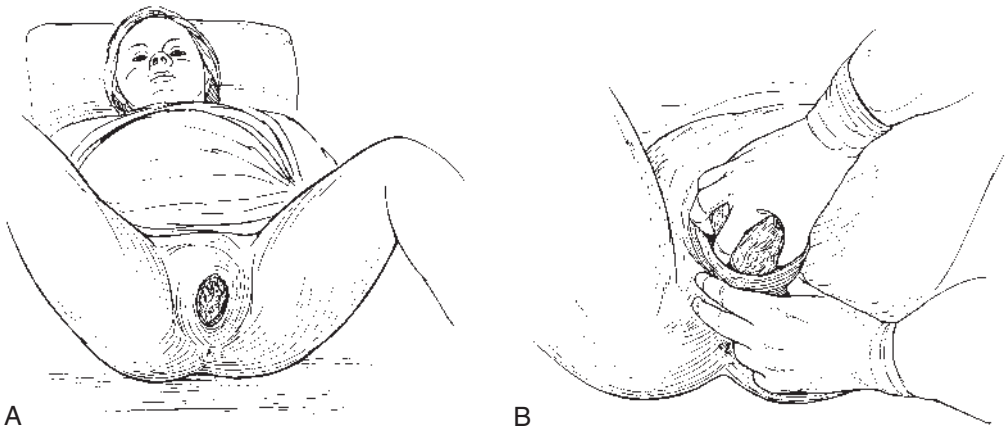

FIGURE AII-12 Vaginal delivery.

before the shoulders are delivered. Reduction can be accomplished by slipping the cord over the head in most instances.

6. Apply traction to head and neck in a downward and forward direction to deliver the anterior shoulder. Minimal lateral extension of the neck reduces the risk of traction injury to the brachial plexus (Fig. AII-12, *D*).
7. Immediately after the delivery of the anterior shoulder, raise the head to allow the posterior shoulder to deliver over the posterior fourchette.
8. Place the infant on the operator's lap, suction the airway, and cut the cord (Fig. AII-12, *E* and *F*).
9. Place the stable newborn immediately on the mother to allow for early contact between mother and infant.

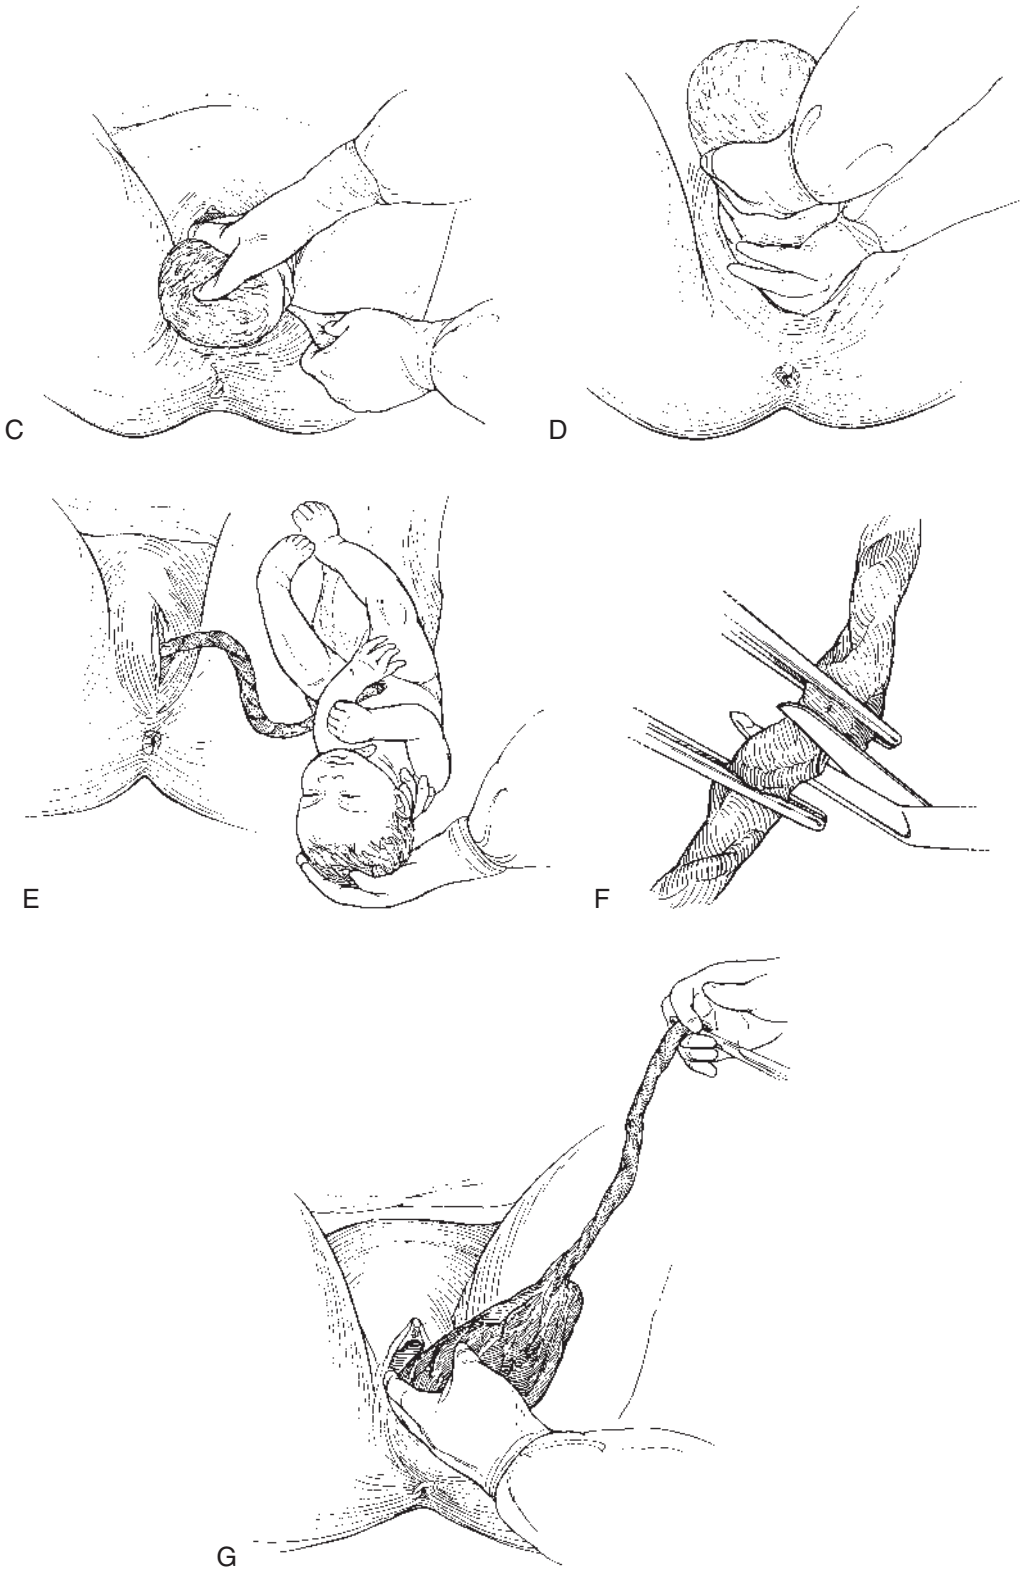

FIGURE AII-12 (Continued)

Third Stage of Delivery

1. After the infant is delivered, the third stage of labor begins.
2. Cross-clamp the cord with a hemostat to allow gentle traction to be applied to the cord, encouraging the progressive delivery of the placenta.
3. Administer oxytocin at this time to encourage placental delivery. Oxytocin administration in the third stage of labor reduces the risk of maternal hemorrhage at no increased risk of retained placenta.
4. The placenta delivers spontaneously after approximately 10 minutes and is inspected to ensure that there are no missing pieces that may suggest that a remnant of a cotyledon remains in the uterus (Fig. All-12, *G*).
5. Massage the uterus to encourage contraction and hemostasis.
6. After the patient's bleeding has slowed, inspect the perineum, vaginal orifice, and cervix for lacerations, which may require specific repair to avoid further bleeding and retain appropriate anatomy.

INDICATIONS

- Patient in active labor
- Fetus in no distress

CONTRAINDICATIONS

- Vasa previa or placenta previa
- Abnormal fetal lie
- Cord prolapse
- Prior classical cesarean section
- Active genital herpes infection
- Fetal deformities

CPT AND ICD-9 CODES

Vaginal delivery

CPT and ICD codes depend on many variables of prenatal and postnatal care. Please refer to manuals for appropriate codes.

B. EPISIOTOMY-LACERATION REPAIR

Key Steps

1. Inject anesthesia.
2. Place an anchor stitch and mucosal closure.
3. Perform deep layer closure.
4. Perform perineal subcuticular closure.
5. Place a final anchor stitch.

INSTRUCTIONS

1. To repair a midline laceration or episiotomy, first inspect the area to determine the extent of the laceration.
2. Identify the vaginal apex, posterior fourchette, and perineal apex.
3. It is critical that the two sides of the posterior fourchette are approximated during the repair.
4. Inject local anesthesia along the edges of the laceration to provide a block for the repair.
5. If an epidural is in place with a good block, local anesthesia is not required.
6. The choice of suture varies by operator, but 3-0 chromic, Dexon, or Vicryl absorbable is often selected for closure.
7. Place an anchoring stitch on the inner, or vaginal, aspect of the laceration just above the apex of the tear or episiotomy.
8. Use a continuous running suture to close the internal vaginal portion of the tear to the posterior fourchette.
9. Once near the posterior fourchette, direct the suture deep to begin a deep layer closure of the perineal aspect of the laceration.
10. Run the suture posteriorly in the subcutaneous and deep layers down to the posterior aspect of the tear.
11. Once at the posterior aspect, perform a subcuticular repair in the posterior to anterior direction along the perineal body.
12. Run the suture continuously to the posterior fourchette until the skin is fully closed.
13. Once the external skin is closed, bring the suture up into the vaginal mucosa and anchor it with another stitch along the posterior vaginal wall to bury the knot.
14. After the repair is completed, perform a digital rectal exam to test the integrity of the repair and to ensure that no sutures were placed through the rectal mucosa.
15. In instances in which there is significant tearing toward the anus, perform the rectal examination prior to the repair to ensure adequate layer-by-layer closure.
16. Clean the patient and reevaluate the amount of lochia to ensure that bleeding is well controlled.
17. Control the pain and swelling of the perineum with oral analgesics and ice packs as needed.

INDICATIONS

- Instrumented delivery
- Shoulder dystocia
- Perineal barrier to effective delivery
- Fetal prematurity
- Breech presentation

CONTRAINDICATIONS

- Extensive vulvar varices

CPT CODES

59300 Episiotomy or laceration repair by other than attending

ICD-9 CODES

664.04 First-degree perineal laceration
664.14 Second-degree perineal laceration

13. REPRODUCTIVE—FEMALE

A. INTRAUTERINE DEVICE (IUD) INSERTION

Key Steps

1. Determine uterine position.
2. Clean cervix with antiseptic solution.
3. Visualize cervix, stabilize with tenaculum if needed.
4. Sound uterus.
5. Mark IUD catheter and insert IUD.
6. Remove catheter, cut strings.

INSTRUCTIONS

1. Before inserting an IUD, the physician must know the position and size of the uterus, which can be determined with a bimanual examination.
2. In most instances, a preprocedure pregnancy test should be performed, and its outcome should be negative.
3. Insert the speculum and clearly visualize the cervix.
4. Clean the cervix with antiseptic solution.
5. Insert the sound and apply pressure to the internal os until it relaxes.
6. A palpable give will be felt when the internal os dilates.
7. It may be necessary to stabilize the uterus with the application of the tenaculum to the cervix.
8. Before being inserted, the IUD must be prepared in a sterile manner.
9. Arm the Paraguard device in a sterile manner within the inner packaging.
10. Retract the Mirena device into the insertion catheter and lock it into position, using the strings at the base of the handle.
11. Set the marker ring on the IUD insertion catheter to match the sound results for both devices.
12. Insert the IUD until the ring is flush to the cervix with the Paraguard device.
13. With the marker ring applied to the cervix, hold the center plunger still while withdrawing the insertion tube out of the cervix.
14. When inserting a Mirena IUD, leave the marker ring 1 cm short of the cervix before releasing the device in the uterus.
15. Pull back the release lever within the handle 1 cm and then advance the catheter up into the uterus so that the marker ring is flush with the cervix.
16. Finally, fully retract the release lever in the handle to free the IUD from the catheter.

17. Withdraw the catheter and see the strings protruding from the os.
18. Trim the strings down to 2 to 3 cm in length.

INDICATIONS
- Patient desires reversible, longer-term contraception
- Treatment of dysfunctional uterine bleeding and cramps with progestin-containing IUD
- Emergency contraception if insertion is performed soon after unprotected intercourse (5 days)

CONTRAINDICATIONS
- Active pelvic inflammatory disease (PID)
- Active cervical infection
- Nonreducible cervical stenosis, preventing insertion
- Poorly defined uterine position and anatomy as determined by pelvic examination
- Allergy to copper for copper-containing IUD

RELATIVE CONTRAINDICATIONS
- Multiple sexual partners, placing patient at risk for PID
- Nulligravida status

CPT CODES
58300 Insertion of IUD (not including device)

ICD-9 CODES
V25.1 Contraceptive management: IUD

B. IUD REMOVAL

Key Steps

1. Visualize cervix, identify IUD strings.
2. Grasp strings with ring forceps.
3. Extract IUD.

INSTRUCTIONS
1. Place the patient in the lithotomy position and insert a speculum to visualize the cervix.
2. Identify the IUD strings.
3. Remove the IUD by firmly grasping the IUD string in the vault, using a ring forceps.
4. With smooth, gentle traction, pull the IUD out of the uterus.

INDICATIONS
- Expired IUD (1 to 5 years for progesterone IUD, 10 years for copper IUD)
- Request for removal
- Overall medical condition that warrants removal
- Pregnancy
- Pelvic inflammatory disease
- Lower genital malignancy
- Dyspareunia
- Uterine perforation
- Partial expulsion
- Some precancerous lesions of cervix or endocervical canal to allow for treatment
- High risk for sexually transmitted diseases
- Menopause
- Desire to become pregnant
- Side effects causing significant patient discomfort
- Any condition that makes a woman ineligible for IUD use

CONTRAINDICATIONS
- None

CPT CODES
58301 IUD removal

ICD-9 CODES
V25.1 Contraceptive management: IUD
V25.42 IUD removal
996.76 IUD causing menorrhagia

C. DIAPHRAGM INSERTION

Key Steps

1. Place patient in lithotomy position.
2. Measure vaginal vault.
3. Determine size of diaphragm.
4. Gently insert and palpate diaphragm-covered cervix.

INSTRUCTIONS
1. Place the patient in the lithotomy position.
2. With index finger, gently determine the distance from the posterior fornix to the inside of the symphysis pubis, which will be the size of the diaphragm. Most women require a 70-mm to 80-mm size.
3. Apply lubricating jelly to the dome and entire rim of the diaphragm. The patient must understand that effectiveness requires use of spermicidal jelly, not lubricant.
4. With the diaphragm folded in half in one hand and the vulva separated with the other, gently insert the diaphragm into the vagina in the direction of the posterior fornix and gently place the anterior edge under the pubis.
5. Determine correct placement by feeling that the cervix is fully covered by the diaphragm.
6. The diaphragm should be comfortable to the patient.
7. Remove the diaphragm by hooking the anterior rim with the index finger and pulling it out through the introitus.
8. Teach the patient to insert, check position of, and remove the diaphragm; provide written instructions.

INDICATIONS
- Desire for self-administered reversible contraception of moderate effectiveness

CONTRAINDICATIONS
- When pregnancy must be prevented owing to maternal medical condition, use more effective method
- Inability to tolerate or understand application of self-insertion diaphragm device
- Not to be used for reliable prevention of sexually transmitted diseases

CPT CODES
57170 Diaphragm or cervical cap fitting with instructions

ICD-9 CODES
V2509 Family planning advice
V2502 Initiation of other contraceptive measures

14. URINARY

A. BLADDER CATHETERIZATION—FEMALE

Key Steps

1. Position patient.
2. Prepare catheter, check balloon.
3. Cleanse labia and urethral meatus.
4. Insert catheter completely into bladder.
5. Inflate catheter balloon.

INSTRUCTIONS
1. Place the patient in the lithotomy position (Fig. All-13, *A*).
2. After donning sterile gloves and draping the patient's genitals, prepare the catheter for insertion.
3. Thoroughly cleanse the labia and the urethral meatus with antiseptic solution (Fig. All-13, *B*).
4. Lubricate the catheter with 2% lidocaine jelly (Fig. All-13, *C*) and gently insert it through the urethra (Fig. All-13, *D*).
5. Pass at least 20 cm of the catheter into the urethra to ensure that it is fully within the bladder (Fig. All-13, *E*).

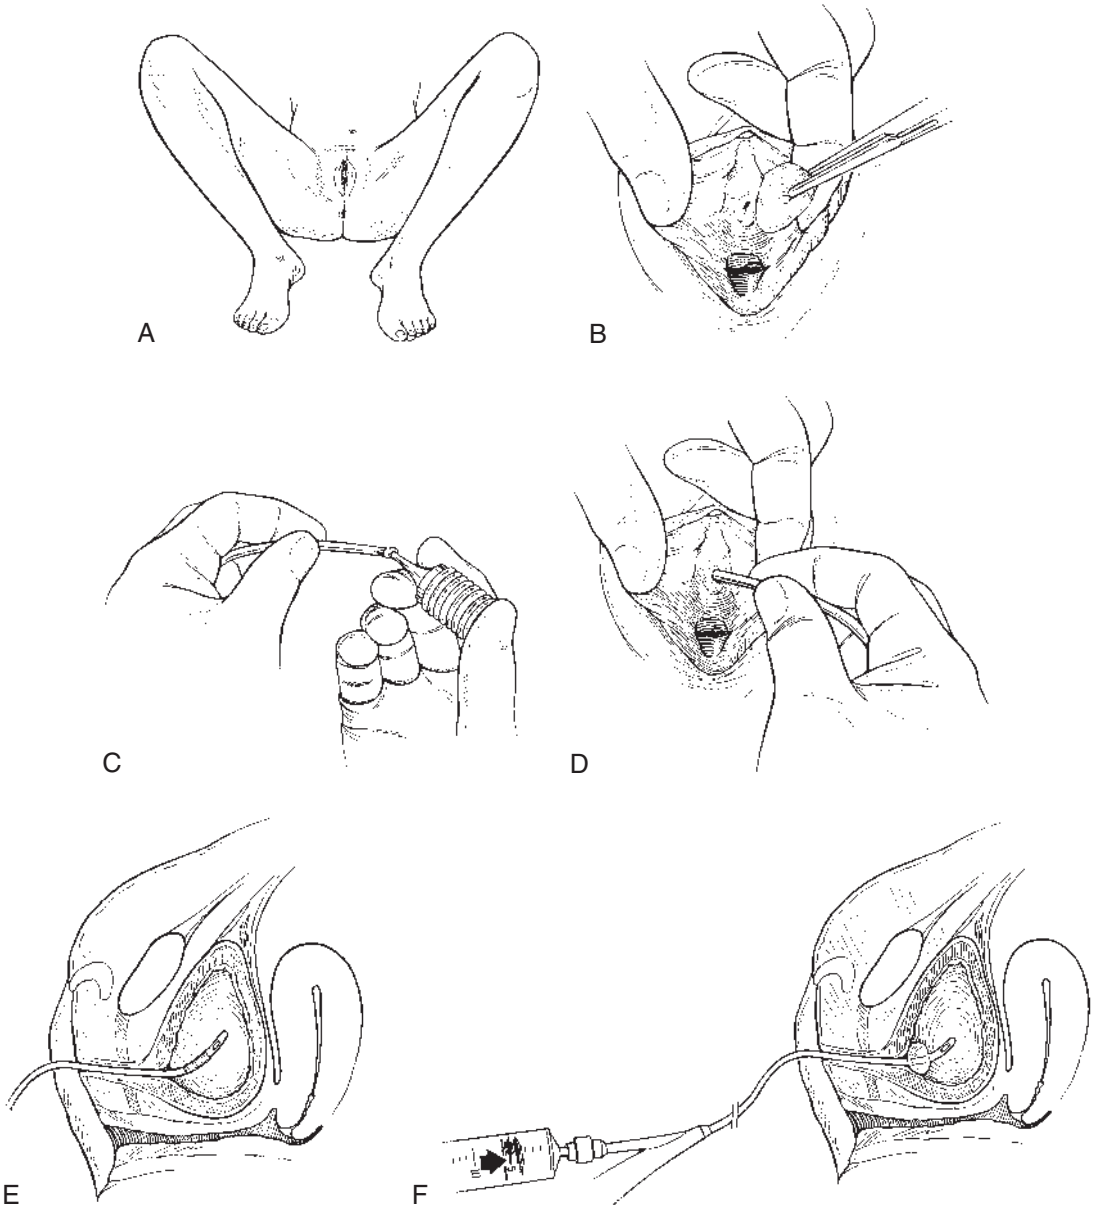

FIGURE AII-13 Bladder catheterization—female.

6. Once urine is obtained, if the catheter is to be left inside, inflate the balloon with 10 ml of sterile water and gently pull the catheter outward to ensure that the balloon is maintaining the catheter in position (Fig. AII-13, *F*).
7. Set up the closed urine collection system and secure the catheter to the patient's thigh with tape.

INDICATIONS
- Relief of urinary obstruction
- Monitoring of urine output
- Obtaining a sterile urine specimen
- Instillation of medications or dyes into the bladder
- Incontinence management
- Measurement of post-void residual volumes

CONTRAINDICATIONS
- Suspected pubic symphysis fracture (blood at the urethral meatus in trauma patient)
- Known fixed obstruction of the urethra (stricture or malignant fixation of urethra)
- Acute infection of prostate or urethra likely

CPT CODES
53670 Simple catheterization

ICD-9 CODES
598.9 Urethral stricture (nontraumatic)
598.1 Urethral stricture (traumatic)
596.0 Bladder neck obstruction (acquired)
788.20 Urinary retention
788.30 Urinary incontinence

B. BLADDER CATHETERIZATION—MALE

Key Steps

1. Position and drape patient.
2. Prepare and lubricate catheter.
3. Cleanse urethra.
4. Advance catheter into bladder.
5. Obtain specimen, remove catheter.

INSTRUCTIONS

1. Place the patient in the supine position.
2. Don sterile gloves and drape the patient's genitals.
3. Lubricate the catheter with 2% lidocaine jelly.
4. Thoroughly cleanse the urethral meatus with antiseptic solution (Fig. AII-14, *A*) and lubricate the urethra (Fig. AII-14, *B*).
5. Gently insert the catheter through the urethra (Fig. AII-14, *C*).
6. Pass the entire length of the catheter into the urethra up to the junction of the catheter and the inflation port (Fig. AII-14, *D*).
7. Once urine is obtained, if the catheter is to be left inside, inflate the balloon with 10 ml of sterile water and gently pull the catheter outward to ensure that the balloon is maintaining the catheter in position (Fig. AII-14, *E*).

INDICATIONS

- Relief of urinary obstruction
- Monitoring of urine output
- Obtaining a sterile urine specimen
- Instillation of medications or dyes into the bladder
- Incontinence management
- Measurement of post-void residual volumes

CONTRAINDICATIONS

- Suspected pubic symphysis fracture (blood at the urethral meatus in trauma patient)
- Known fixed obstruction of the urethra (stricture or malignant fixation of urethra)
- Acute infection of prostate or urethra likely

  for uric acid calculi, 1062
Almotriptan, for migraine headaches, 430t
Alocril, for conjunctivitis, 257
Aloe vera (Dermaide), 394
Alopecia, **41-42**
  clinical algorithm, 1221f
  differential diagnosis of, 1117
  nonscarring, 1117
  scarring, 1117
Alopecia areata, 41, 41f
  treatment for, 42
Alosetron, for irritable bowel syndrome, 557
Alpha thalassemia, 1005
α-adrenergic blockers, 517
  advantages of, 517
  disadvantages of, 517
  for hypertension, 517
  for thromboangiitis obliterans, 1008
Alpha-lipoic acid, for ataxia telangiectasia, 117
Alpha-1-antitrypsin, serum, 1350
Alpha-1-antitrypsin deficiency, **43**
Alpha-1-fetoprotein, 1366
Alprazolam
  for panic disorder, 743
  for phobias, 782

Alprazolam *(Continued)*
for premenstrual dysphoric disorder, 822
for premenstrual syndrome, 823
Alprostadil
for erectile dysfunction, 367
for Raynaud's phenomenon, 870
for thromboangiitis obliterans, 1008
ALS, **57**
ALT, 1350
Altered mental status, in dialysis patients, 1137-1138
Alternative medicine/therapy
for ataxia telangiectasia, 117
for chronic fatigue syndrome, 228
for claudication, 242
for cognitive impairment, mild, 646t
for decubitus ulcer (pressure ulcer), 284
for endometriosis, 350
for inclusion body myositis, 540
for mastitis, 619-620
for subdural hematoma, 981
Altitude sickness, **44-45**
Aluminum, serum, 1350
Alveolar consolidation, 1117
Alveolar hemorrhage, 1117
Alveolitis, extrinsic allergic. *See* Hypersensitivity pneumonitis.
Alzheimer's disease, **46-47**
Amalgam tattoo, 1176
Amanita intoxication, 669
Amanita phalloides, 669f
Amantadine (Symmetrol)
for avian influenza, 549
for Huntington's disease, 495
for influenza, 549, 798
avian influenza, 549
for multiple sclerosis, 664
for Parkinson's disease, 747
for viral pneumonia, 798
Amaurosis (blindness), childhood, 1126-1127
Amaurosis fugax, **48**
Amblyomma americanum, 1199
Amblyomma maculatum, 1199
Amblyopia, **49**
Ambulatory phlebectomy, 1074
Amebiasis, **50**
Amebiasis serologic test, 1350
Amebic abscess, hepatic, **7-8**
Amebic dysentery, **50**
Amenorrhea, **51-53**
bromocriptine in, success rate of, 53f
differential diagnosis of, 806, 1117
lactation amenorrhea method of contraception, 259
primary
diagnostic evaluation of, 1222f
tests for, 1222b
secondary, evaluation of, 1223f
American Tinnitus Association, 1024
American trypanosomiasis, **217-218,** 217f
American Urological Association, guideline recommendations for bladder cancer, 156b
AMI, **639-640**
Amicar, 448
Amikacin, for nocardiosis, 703
Amiloride
for ascites, 103
for Bartter's syndrome, 137
Aminocaproic acid (EACA, Amicar), 448
Aminoglutethimide, for Cushing's disease, 786
Aminoglycosides
for bacterial meningitis, 633t
for blepharitis, 159
for cat-scratch disease, 203
for cellulitis, 207
for liver abscess, 8
Aminoglycosides *(Continued)*
for otitis externa, 728
for pancreatitis, 740
for *Pseudomonas* infections, 279
for pyelonephritis, 860
for urinary tract infections, 1060
Aminolevulic acid (d-ALA), 1350
Aminotransferases, for hepatitis, 464
Amiodarone, for atrial fibrillation, 121
Amisulpride, for tardive dyskinesia, 997
Amitriptyline (Elavil)
for burning mouth syndrome, 183
for complex regional pain syndrome, 252
for diabetic polyneuropathy, 310
for interstitial cystitis, 553
for postconcussive syndrome, 815
for Ramsay Hunt syndrome, 868
AML. *See* Leukemia.
Amlodipine, for Raynaud's phenomenon, 870
Ammonia
colonic production of, reduction of, 455
serum, 1350
Amnesia/amnestic disorder, **54-55,** 1117-1118
Amnionic fluid alpha-fetoprotein elevation, 1118
Amoxicillin
for anaerobic infections, 58
for bronchitis, acute, 31
for *Chlamydia* genital infections, 223
for Epstein-Barr virus infection, 365
for *H. pylori* gastritis, 400
for *H. pylori* infection, 444
for Lyme disease, 602
for otitis media, 730
for paronychia, 748
for peptic ulcer disease, 766-767
for perirectal abscess, 12
for pharyngitis/tonsillitis, 780, 791
for prepubescent vulvovaginitis, 1091
for salmonellosis, 906
for sinusitis, 941
for tick bites, 149
for typhoid fever, 906, 1055
Amoxicillin-clavulanate (Augmentin)
for acute bacterial sinusitis, 941
for bite wounds, 148
for mastitis, 619
for paronychia, 748
for pharyngitis/tonsillitis, 791
for prepubescent vulvovaginitis, 1091
for sialadenitis, 934
for urinary tract infections, 1060
Amphotericin B
for aspergillosis, 106
for coccidioidomycosis, 247
for cryptococcosis, 272
for histoplasmosis, 482
for leishmaniasis, 579
for mucormycosis, 659
for otitis externa, 728
for pulmonary blastomycosis, 157
for sporotrichosis, 960
for thrombophlebitis, superficial, 1011
Ampicillin/sulbactam
for appendicitis, 94
for bacterial meningitis, 632, 633t
for bacterial pneumonia, 793
for bite wounds, 148
for cholangitis, 224
for endometritis, 351
for epiglottitis, 361
for Epstein-Barr virus infection, 365
for listeriosis, 595
for nocardiosis, 703
for pancreatitis, 740
for pelvic inflammatory disease, 761
for perirectal abscess, 12
Ampicillin/sulbactam *(Continued)*
for peritonitis, secondary, 774
for pyelonephritis, 860
for retropharyngeal abscess, 890
for tropical sprue, 1043
for typhoid fever, 1055
AMS, **44-45**
Amyl nitrate, for priapism, 827
Amylase
serum, 1350
urine, 1388
Amyloid A protein, serum, 1350
Amyloidosis, **56**
restrictive cardiomyopathy caused by, 195, 195f
Amyotrophic lateral sclerosis, **57**
ANA. *See* Antinuclear antibody.
Anaerobic infections, **58**
Anafranil. *See* Clomipramine (Anafranil).
Anagrelide, for thrombocytosis patients, 1009
Anal abscess and fistula, 1118
Anal fissure, **59**
Anal incontinence, 1118
clinical assessment, 1260b
differential diagnosis, 1161
Anal ulcer, **59**
Anal ulceranorectal fissure, **59**
Analgesics. *See also specific analgesic.*
for back pain control, 1231f
for cervical disk syndromes, 212
for chronic pain management, 233
WHO analgesic ladder, 233f
for cluster headache, 428
for dyspareunia, 325
for fractures, vertebral compression, 1080
for myocardial infarction, 676
for priapism, 827
for tabes dorsalis, 993
WHO analgesic ladder, 233f
Anaphylactoid purpura. *See* Henoch-Schönlein purpura.
Anaphylactoid reaction. *See* Anaphylaxis.
Anaphylaxis, **60**
blood transfusion reaction, 1032t
differential diagnosis, 1118
treatment with intramuscular or oral pharmaceuticals, 1419t
Anaplasma phagocytophilum, **491**
Anaplastic carcinoma of thyroid, 1013-1014
Anaprox. *See* Naproxen (Anaprox).
Anarthritic rheumatoid syndrome, **809,** 809t
ANCA, 1351
Ancylostoma duodenale (hookworm), 487
Androgen deprivation therapy, for prostate cancer, 836
Androgen excess, reproductive-age women, 1118
Androgenetic alopecia, 41
treatment for, 42
Androgens, for hereditary angioedema, 75
Androstenedione, serum, 1350
Anemia
algorithm for diagnosis, 1224f
aplastic, **62,** 1118
acquired, 1118
due to drugs and chemicals, 1119
inherited, 1118
of paroxysmal nocturnal hemoglobinuria, 750
autoimmune hemolytic, **63**
characteristics of, 749t
of chronic disease, **61,** 1223f
Cooley's. *See* Thalassemias.
drug-induced, 1119
hemolytic, SLE and, 991
hypochromic, 1119
hypoplastic, **62**
iron deficiency, **64-65**
differential diagnosis of, 64t

Anemia *(Continued)*
low reticulocyte count, 1119
macrocytic, 1119
clinical algorithm for, 1225f
Mediterranean. *See* Thalassemias.
megaloblastic, 1119-1120

sodium, 1017
tincture of, 748
Iodine-131 radiotherapy
for hyperthyroidism, 519
for thyroid carcinoma, 1013
Iodoquinol, for amebiasis, 50
Ionizing radiation, 865
Ipilimumab, for melanoma, 628
Ipratropium, for chronic obstructive pulmonary disease, 232
Irinotecan (Camptosar), for colorectal cancer, 250
Iron, ocular, 709, 709f
Iron absorption or utilization, drugs that interfere with, 1119
Iron chelating therapy, for sideroblastic anemia, 67
Iron deficiency anemia, **64-65**
differential diagnosis of, 64t
Iron overload, 1162
acquired, 1162
focal sequestration of iron, 1162
hereditary, 1162
perinatal, 1162
Iron saturation (% transferrin saturation), 1375
Iron-binding capacity
serum, 1375t
total, 1374-1375, 1375t
Irritable bowel syndrome, **557-558**
Irritable colon, **557-558**
Irritable heart, **817-818**
Ischemia
mesenteric, nonocclusive, 1169
myocardial, causes of, 1171-1172
renal disease, 1313f
Ischemic ARF, **1051**
Ischemic colitis, nonocclusive, 1162
Ischemic optic neuropathy, 1203
Ischemic spinal cord syndromes, 1194
Ischial gluteal bursitis (weaver's bottom), 185
Isoimmunization
D, prevention of, 892
risk factors for, 892
Isolated memory impairment, **646**
Isolated mononeuropathy, 1170
Isoniazid, for pulmonary tuberculosis, 1048
Isoproterenol, for heart block, complete, 436
Isosorbide dinitrate, for achalasia, 21
Isosorbide dinitrate-hydralazine, for heart failure, 440
Isotretinoin (Accutane)
for acne vulgaris, 24
for hidradenitis suppurativa, 476
for histiocytosis X, 480
for rosacea, 900
Isradipine, for Raynaud's phenomenon, 870
ITP, **538,** 1413t
Itraconazole (Sporanox)
for aspergillosis, 106
for candidiasis, 186
for CNS blastomycosis, 158
for coccidioidomycosis, 247
for disseminated extrapulmonary blastomycosis, 157
for fungal vulvovaginitis, 1090
for histoplasmosis, 482
for onychomycosis, 710
for paronychia, 748
for sporotrichosis, 960
for tinea capitis, 1018
IUD (intrauterine device), 259-260
copper, 340
IVC thrombosis. *See* Budd-Chiari syndrome.
Ivermectin (Mectizan)
for cutaneous larva migrans, 278
for filariasis, 387
for lice, 757
for scabies, 909
Ixodes ticks, 602
differential diagnosis of, 1199

Vestibular neuronitis, **571, 1082**
Vestibular neuronopathy, acute, **571**
Vestibular schwannoma, **25**
Vestibular suppressants, 571
VHL disease, **1084-1085**
Viagra. *See* Sildenafil (Viagra).
Vibrio cholerae, 227
food poisoning, 391
Vibrio parahaemolyticus, 391-392
Vibrio vulnificus infection
cellulitis, 207
food poisoning, 392
Vidarabine, for herpes zoster, 472
Vidian neuralgia. *See* Cluster headache.
Vigabatrin, for tuberous sclerosis, 1050
Vinblastine. *See* Chemotherapy.
Vincent's stomatitis, **409**
Vincristine
for hypereosinophilic syndrome, 507
for multiple myeloma, 662
for peripheral hereditary neuropathy, 701
for thrombocytopenia, 992
Viral capsid antigen, 1365t
Viral keratitis with ulceration. *See* Corneal ulcers.
Viral neurolabyrinthitis, **571**
Viral parotitis. *See* Mumps
Visceral sporotrichosis, 960
Viscosity, serum, 1391
Vision loss
acute painful, 1203
acute painless, 1203
amaurosis fugax, **48**
in children, 1203
chronic progressive, 1203
monocular transient, 1203
with mushroom poisoning, 669t
pediatric age blindness, 1126-1127
Vita-Dye, for vitiligo, 1083
Vitamin A
for measles, 624, 798
for oral hairy leukoplakia, 592
for retinitis pigmentosa, 886
Vitamin B_6
for hyperemesis gravidarum, 506
for premenstrual syndrome, 823
for sideroblastic anemia, 67
for tardive dyskinesia, 997
Vitamin B_{12}, 1391
for celiac disease, 206
drugs that interfere with, 1119
for gastrectomy patients, 399
supplements, 1043
for tropical sprue, 1043
Vitamin C
for complex regional pain syndrome, 252
for decubitus ulcer (pressure ulcer), 284
Vitamin D
for amenorrhea, 52
for chronic inflammatory demyelinating polyneuropathy, 230
deficiency, 1356t
1, 25 dihydroxy calciferol, 1391
for hypocalcemia, 691
for hypoparathyroidism, 526
for osteoporosis, 725
-resistant rickets, 898
Vitamin E
for ataxia telangiectasia, 117
for Friedreich's ataxia, 393
for hot flashes, 490
for menopause, 636
for Peyronie's disease, 779
for retinitis pigmentosa, 886
for tardive dyskinesia, 997
for telangiectasia, ataxia, 117
Vitamin K, 582, 1391
deficiency, laboratory findings in, 316
Vitiligo, **1083,** 1083f
Vitreous hemorrhage, 1203
Vivactil, for narcolepsy, 687
Vivelle. *See* Estradiol (Estrace).
Vocal card paralysis, 1203
Volume depletion, 1203-1204
Volume excess, 1204
Vomiting. *See* Nausea and vomiting.
von Hippel-Lindau disease, **1084-1085,** 1084t
von Recklinghausen disease, 694
von Willebrand factor, 1392
von Willebrand's disease, **1086**
genetic and laboratory findings in, 1086, 1086t
Voriconazole
for aspergillosis, 106
for CNS blastomycosis, 158
VSD. *See* Ventricular septal defect.
Vulva
adenocarcinoma of, 1087
basal cell carcinoma of, 1087
melanoma of, 1087
postmenopausal atrophy of, 1089, 1089f
pruritus, 1185. *See* Pruritus vulvae.
squamous cell carcinoma of, 1087
verrucous carcinoma of, 1087
Vulvar cancer, **1087**
FIGO staging, 1087t
treatment algorithm for, 1340f
Vulvar lesions, differential diagnosis of, 1204
Vulvar sarcoma, **1087**
Vulvodynia, **841**
Vulvovaginitis
bacterial, **1088**
C. trachomatis, 1091
candidal, symptoms of, 186
estrogen-deficient, **1089,** 1089f
fungal, **1090**
gonococcal. *See* Gonorrhea.
H. influenzae, 1091
N. gonorrhoeae, 1091
prepubescent, **1091**
S. aureus, 1091

Vulvovaginitis candidiasis, 186
vWD. *See* von Willebrand's disease
VZIG. *See* Varicella-zoster immune globulin.

W

Waldenström's macroglobulinemia, **1093-1094**
monoclonal immunoglobulin protein, properties of, 1093t
Walking pneumonia. *See Mycoplasma* pneumonia.
"Wandering pacemaker," **660,** 660f
Warfarin therapy
for antiphospholipid antibody syndrome, 88
for atrial fibrillation, 121
for deep vein thrombosis, 286
for pulmonary embolism, 852
for pulmonary hypertension, 855
for stroke, 972
for transient ischemic attack, 1033
for venous thrombosis, 504
Warts, **1095-1096**
anogenital. *See* Condyloma acuminatum.
common, **1095-1096,** 1095f
filiform, **1095-1096**
flat, **1095-1096**
genital, **1095-1096.** *See also* Condyloma acuminatum.
treatment of, 1096
mosaic (cluster of), **1095-1096**
plantar, **1095-1096**
differential diagnosis of, 1146
treatment of, 1096
venereal, **1095-1096.** *See also* Condyloma acuminatum.
Water-hammer pulse, 92
Water-rat trapper's disease. *See* Tularemia.
Waterston shunt, 1004
Weakness. *See also* Fatigue.
acute, emergent, 1205
gradual onset, 1205
muscle. *See* Muscle weakness.
neuromuscular, clinical algorithm for, 1343f
nonneuromuscular causes, 1205
Weaver's bottom (ischial gluteal bursitis), 185. *See also* Bursitis.
Wegener granulomatosis, 1121

Weight gain
clinical algorithm for, 1344f
differential diagnosis of, 1205
obesity. *See* Obesity.
Weight loss
anorexia. *See* Anorexia/anorexia nervosa.
arthritis and, 1122
bulimia nervosa. *See* Bulimia nervosa.
causes of, 1205
involuntary, 1345f
"treatment" for obesity, 706, 706t
Weil's syndrome, 582. *See also* Leptospirosis.
Wenckebach (Mobitz type I) second-degree AV block, 437, 437f
Wernicke encephalopathy, **1098-1099**
Wernicke syndrome, **1098-1099,** 1098t
ophthalmoplegia, causes of, 1176
Wernicke-Korsakoff syndrome, **570**
Wernicke's superior hemorrhagic polioencephalitis, **570**
West Nile virus infection, **1100**
Westergren, 1365
Wheals. *See* Urticaria
Wheezing
causes of, 1129, 1205
in children, 1205
differential diagnosis of, 1205
Whiplash, **1101**
Whiplash-associated disorders, 1101, 1101t
Whipple's disease, **1102**
eye lesions, 1121
Whipple's procedure, 738
White blood cells, 1361
urine, microscopic examination of, 1389t
White clot syndrome. *See* Heparin-induced thrombocytopenia.
White lesions
oral, 1176-1177
stomatitis with, 967
vulvar, 1204
White Petrolatum, 964
White spongy nevus, 967, 1177
WHO analgesic ladder, 233f
Whooping cough, **777,** 777f
Wide QRS beats, tachycardia *vs.,* 1331t
Wild hare disease. *See* Tularemia.
Williams factor, 1360t
Wilms' tumor, **689,** 689f
Wilson's disease, **1103,** 1103f
Withdrawal (contraceptive method), 259
WM, **1093-1094**
Wolff-Parkinson-White syndrome, **1104-1105**
bypass tract in, 1104f
ECG features of, 751, 1104, 1104f
palpitations with, 1178
Worms, **102**
Wound botulism, **164**
Wounds
bites. *See* Bites.
burn, 184
WPW. *See* Wolff-Parkinson-White syndrome
Wrist and hand pain, in different age groups, 1205-1206
adolescence (10 to 18 yr), 1205
adulthood (30 to 50 yr), 1205
childhood (2 to 10 yr), 1205
early adulthood (18 to 30 yr), 1205
old age (50+ yr), 1205
Wrist pain, 1206
Writer's cramp, 329, 329f. *See also* Dystonia.
Wry neck, **1025,** 1025f. *See also* Dystonia.
Wuchereria, 386
Wuchereria bancrofti, 386

X

Xerophthalmia, 1206
Xerostomia, 1206
X-linked hypophosphatemic rickets, 898, 898f
X-ray, chest. *See* Chest X-ray.
X-ray, on air-space opacification, 1116
47, XXY hypogonadism, **569**
Xylocaine
for de Quervain's tenosynovitis, 297
for trigger finger, 1041
for trochanteric bursitis, 1042
Xyrem, for narcolepsy, 687

Y

Yeast infection, 841
Yellow fever, **1106**
Yellow fever vaccine, 1431t
Yersinia enterocolitica food poisoning, 391
Yersinia pseudotuberculosis food poisoning, 391
Yuppie flu, **228**

Z

Zaditor, for conjunctivitis, 257
Zalcitabine (DDC), for AIDS/HIV, 27
Zanamivir
for influenza, 547
for viral pneumonia, 798
Zeasorb. *See* Miconazole (Lotrimin, Monistat, Zeasorb).
Zenker's (pharyngoesophageal) diverticulum, **1107-1108,** 1107f, 1108f
Zidovudine (AZT), for HIV, 27, 493-494
for AIDS/HIV, 493
Zinc/zinc supplementation
for cholera, 227
for decubitus ulcer (pressure ulcer), 284
for macular degeneration, 611
for Wilson's disease, 1103
Ziprasidone (Geodon)
for bipolar disorder, 146-147
for Tourette's syndrome, 1026
Zithromax. *See* Azithromycin (Zithromax).
Zollinger-Ellison syndrome, 767, **1109**
differential diagnosis of, 1179
Zolmitriptan
for cluster headache, 428
for migraine headaches, 430t
Zoloft. *See* Sertraline (Zoloft).
Zostrix, for herpes zoster, 472
Zosyn. *See* Piperacillin-tazobactam.
Zovirax. *See* Acyclovir (Zovirax).
Zygomycetes infection, **659**
Zyprexa. *See* Olanzapine.
